All communications to be addressed to the Branch Manager BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele Address: Triform, Wesdo—London.
Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Suitable house, with 2 reception, 4 bedrooms, etc., secluded garden. Price for freehold £1,650, of which £900 could remain on mortgage. Premium £800.
22. ESSEX.—Very old established PRACTICE, situated in pleasant country district, in growing area about 30 miles from London, and few miles from the sea. Cash receipts average nearly £900 p.a., including panel of 600. House contains surgery and waiting room, 3 reception, 5 bedrooms, bathroom, etc. Garden. Garage. Gas, but electric light available. Moderate rental. Premium 1½ years' purchase.
23. PARTNERSHIP.—YORKSHIRE.—LARGE CITY.—A one third share, with succession to the whole Practice in about one year's time, is offered in a rapidly increasing PRACTICE, producing for the last 12 months approximately £2,300, including panel of 1,500. Appts worth £150. A suitable house will be vacant shortly. Premium £1,200. Large scope for further development.
24. WITHIN 20 MILES OF LONDON (WEST).—Rapidly developing district.—PARTNERSHIP.—A half share in a well established good middle class Practice, averaging over £3,500 p.a. Panel of 1,100 and appts worth £100 p.a. Fees 3/6 to 21/-. Good corner house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £2,100. Premium 2 years' purchase.
25. CHESHIRE.—NEAR COAST.—Old established good mixed class PRACTICE, averaging for the past 3 years nearly £1,600, including panel of 1,280. Very good house in 3 acres of ground, with 2 reception, 4 bedrooms, etc. Rent on lease £85 p.a. *Premium* £2,500.
26. HOME COUNTIES.—Within 30 mins.' run of London.—Old-established mixed class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.
27. SURREY.—Increasing residential district, with good train service to town.—Well established good general PRACTICE, offering great scope. Gross cash receipts for last 12 months nearly £3 200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.
28. NORTH OF ENGLAND.—GOOD TOWN.—A one third share required in a very sound PRACTICE *averaging* about £5,000 p.a. Junior partner must be well qualified, not over 35, and interested in golf. Suitable house available. Premium 2 years' purchase.

ASSISTANTS REQUIRED.—(1) LONDON, S.W.—Outdoor. £500 p.a., unfurnished house. (2) LINCOLN.—Outdoor. £300 p.a., all found. (3) NORFOLK.—Outdoor. £400 p.a., with view to Partnership. (4) LONDON, N.W.—*Indoor.* £300/£350 p.a.

Full Schedule of Terms and Conditions will be forwarded on application.

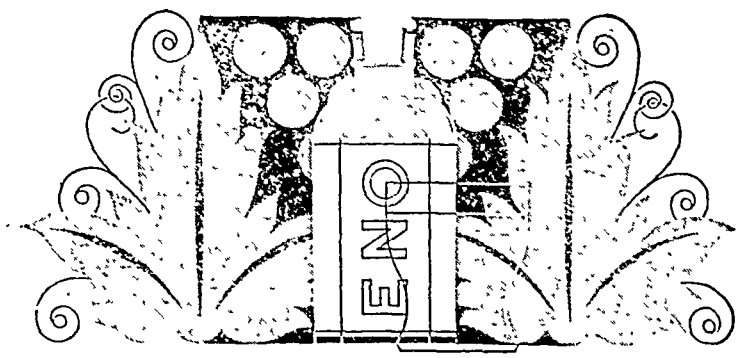
Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

NUTRITIONAL ANÆMIA IN INFANCY

The investigations into the nutritional anæmia of Infancy have been brought to a successful conclusion, and the results fully reported in the Medical Research Council Report (Special Report Series No. 157) 1931.

The milk food used in this extensive work is now available to Medical Practitioners under the name of

HĒMOLAC



(Full Cream Milk Powder with Iron Ammonium Citrate)

The exhibition of Hēmolac rapidly restores the hæmoglobin percentage of anæmic infants to a normal figure. It has also been demonstrated that Hēmolac acts as a prophylactic against the common catarrhal infections of the respiratory and alimentary tracts. The morbidity rates of the infants supplied with the extra iron in Hēmolac, was less than half that of the controls fed on diets without additional iron. It is significant that ultra-violet ray and vitamin therapy were without effect.

Clinical samples and literature will gladly be sent on request to any Medical Practitioner

PURGATIVES AND MALNUTRITION

The dangers attending the administration of irritant purgatives to delicate and debilitated patients have long been recognised.

Whilst a certain amount of immediate relief may be thus obtained, the disturbing effect on the autonomic nervous system and the malnutrition resulting from irritation of the absorptive mechanism frequently outweigh the temporary alleviation. There appears, also, to be considerable risk of malnutrition in the constant use of laxatives of the so-called lubricating type. The covering of the mucous membrane of the intestines with a thin coating of oil can hardly fail to lessen the absorption of aliment. Moreover, it was found by Channon and Collinson that a portion of the mineral oil is liable to be absorbed and to accumulate in the liver. The pathologic possibilities of such accumulation need no stressing.

For the relief of moderate degrees of constipation, in cases in which the fullest nutrition is important, no safer or more reliable laxative can be found than an effervescent preparation of the standard of Eno's "Fruit Salt."

In Eno's "Fruit Salt," it is claimed, we have at our disposal a carefully compounded, pure and standardised preparation, entirely free from the harsh and disagreeable sulphates of soda and magnesia. Eno's "Fruit Salt" has been used and prescribed by thousands of doctors for over half a century, during which time its reputation has become world-wide.

ENO'S "FRUIT SALT"

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

PANTERIC TABLETS

An Improved Method of Administering Pancreatin.

IN order to make effective the oral administration of pancreatin, it is necessary to exhibit it in tablets capable of resisting the inactivating effect of the gastric juice. Parke, Davis & Co. have succeeded in perfecting a coating which contains no salol and is therapeutically inert, yet is able to prevent the disintegration of the tablet in the stomach and permit the liberation of the pancreatin in the intestine, where alkaline secretion provides the optimum condition for its action.

Five-grain triple-strength Pancreatin tablets so coated are issued under the name "Panteric Tablets". They are indicated for the relief of symptoms consequent upon incomplete digestion of proteins, also in diabetes as an adjunct to insulin treatment, in food asthmas and urticarias, in tuberculosis, and in fermentative colitis. Panteric *Compound* Tablets contain, in addition to 4 grs. of pancreatin, 3 4 gr. each of sodium glycocholate and sodium taurocholate (bile salts) which assist in the assimilation of fats and lessen the liability of intestinal contents to putrefaction.

Panteric Tablets and Panteric Compound Tablets are supplied in bottles of 25, 100 and 500. A booklet giving full particulars will be sent on request. [Half-strength (2-1/2 grs.) Panteric Tablets are also available in the same size packings].

PARKE, DAVIS & CO., 50 BEAK STREET, LONDON, W.1.

Laboratories: Hounslow, Middlesex. Inc. U.S.A., Liability Ltd

USED IN DERMATOLOGY, Antiphlogistine acts exclusively as a stimulating topic. Whether in cases of exfoliative Dermatitis, dry or impetiginous Eczema, Lichen or Psoriasis, the results are usually rapid and assured.

In Eczema, the intolerable itching disappears, thus affording the patient a complete rest.

The effect of internal medication is intensified and prolonged through the detersive action of Antiphlogistine applied concurrently or before commencing specific treatment.

FLATULENCE AND ALIMENTARY FETOR

MANY conditions are associated with flatulence, some of which frequently give rise to embarrassment of distant organs.

Dyspepsia, catarrh and ulceration of the stomach and intestine, cancer, dysentery, and other diseases of the alimentary canal itself, neurasthenia, and diseases of the heart, liver and pancreas, to name only a few, may all be associated with flatulence and intestinal flatus.

Some of the diseases of the intestine, such as dysentery and cancer, are often also associated with horrible fetor of the evacuations.

The accumulation of flatus in the stomach and intestine is liable to embarrass the action of the heart and lungs, giving rise to dyspnœa, disordered action of the heart, faintness and even anginal attacks.

Both the flatulence and fetor are the result of abnormal fermentation and putrefaction of the contents of the alimentary canal; apart from treatment of the condition itself, it can be rationally controlled by the use of an efficient intestinal disinfectant. For this purpose, Kerol, the most potent germicide, being unabsorbed and non-toxic, is unsurpassed, and can be safely administered in sufficient amount to exert its germicidal action.

When the fermentation is located in the stomach, KEROL CAPSULES (Gastric) m. 3, should be administered: one or two may be given three or four times a day after meals.

When there is intestinal flatus and fetor, the keratin-coated KEROL CAPSULES m. 3, should be used, the dose being one to three after meal.

Intestinal **Disinfection**

FOR INTERNAL TREATMENT OF
GONORRHOEA, URETHRITIS AND OTHER AFFECTIONS
OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably
FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & CO., 15, Gt. St. Andrew St., W.C.2.

SANTAL MIDY

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

For Acute or Chronic Cases of Hyperacidity

For Gastric Duodenal or Pyloric Ulcers

M.232.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Alasil

Food Poisoning—
The Kaylene Treatment

The following letter has been received.

Messrs. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to————. ————, M.B.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contraindicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr Iodine is employed. Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform Ointment."

"Festering wound on left heel—when first seen was about the size of a shilling, with a good deal of pus. Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

Thyroid Medication

A new preparation of the pioneers in endocrine therapy

The name given to Reed & Carnrick's new thyroid speciality is Thyracoids.
"Thyracoids" consist of iodo-thyroglobulin, standardised biologically. They can be depended upon to be of uniform strength and to represent the entire activity of desiccated thyroid.
Thyracoids may be used advantageously in all cases where thyroid medication is indicated.

Packings: Bottles of 100 $\frac{1}{16}$, $\frac{1}{4}$, 1 and 2 grain tablets
Plain or enteric coated.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

Compound Syrup of Hypophosphites

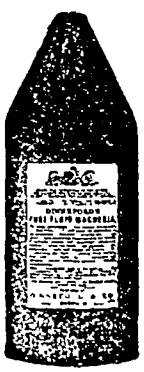
Regesan

FRUIT SALINE

AN agreeable effervescent preparation containing the fruit acid of the grape and antacids which correct minor disturbances of the stomach, liver and bowels.

Regesan Fruit Saline has been found to be of considerable value when the promotion of increased peristalsis has been desirable. Free from sugar, it may be prescribed for Diabetics and others who cannot tolerate sugar in any form



OBTAINABLE FROM

The Boots Chemists

OVER 900 BRANCHES IN GREAT BRITAIN

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

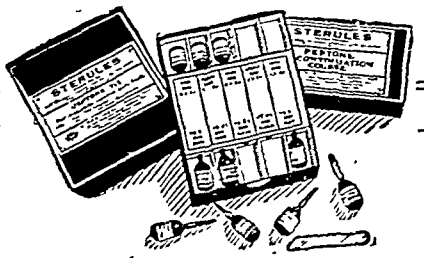
DINNEFORD & CO. LTD.

Medisoap

MIDGLEY'S MEDICATED SOAP Regd.

ACNE VULGARIS

The use of a suitable form of Sulphur in the pustular stage of Acne is generally effective in preventing the formation of indelible cicatrices. Several of the standard Medisoap exhibit active Sulphur both alone and in combination, and are ideal for the treatment of facial acne and the greasy and scurfy condition of the scalp with which it is so frequently associated. The following Medisoaps are often prescribed by leading dermatologists for this purpose:



MEDISOAP No. 4	SULPHUR (Alkaline)
MEDISOAP No. 9	SULPHUR (Superfatted)
MEDISOAP No. 17	SULPHUR and RESORCIN
MEDISOAP No. 18	SULPHUR and NAPHTHOL

Several other formulae containing Sulphur are available. Full particulars with notes on their practical application are given in "Medisoap Therapy," a Prescriber's index to Medisoaps, which will be sent to members of the medical profession on application to:

BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN

Carbohydrates

Compared with maternal milk the carbohydrate content of cows' milk is considerably deficient, but in Lactogen—by suitable modification—this deficiency has been rectified.

Unlike ordinary dried milks, in which the carbohydrate is in the same proportion as in the raw milk, LACTOGEN CONTAINS PRACTICALLY THE SAME AMOUNT OF CARBOHYDRATE AS WOULD BE FURNISHED BY HUMAN MILK.

Lactogen is neither a new nor untried [illegible]. First introduced in Australia, it h[illegible] years enjoyed a large sale in ove[illegible]

Lactogen is prepared in England by Nestlé's—famous for more than fifty years for the purity of their milk products—from the pure, fresh milk of specially selected herds, grazing on picked English farms.

SALTAIR SURGICAL SERVICE

Safeguards *of* Satisfaction

EVERY Salt Appliance carries two warrantees.

- **1.** The well-known Saltair Brand, representing the practical experience of 138 years, during which period they have worked with the Medical Profession.
- **2.** The equally famous Saltair Guarantee which covers both the attendant Medical Practitioner and patient alike.

Medical Practitioners will appreciate the *only* inference that can be drawn of a firm that substantiates its Trade Mark in such a tangible way.

ESTABLISHED 1793

The Cure of Varicose Ulcer

Ulcer of 1½ years' duration.

Method of application.

After 13 weeks' treatment with Elastoplast.

Here is proof—

Vide British Medical Journal, August 8th, 1931, pp. 266/7. Paper read in the Section of Dermatology, British Medical Association.

"The treatment employed by the speaker consisted essentially in supporting the leg by means of a bandage of elastic sticking plaster which could not move when once applied, and which adjusted itself to the shrinkage of the leg. The bandage was changed only at considerable periods. The speaker had cured 525 cases of ulcer of a total area of 25 square feet."

A later speaker:—"As regards dermatitis, he had never seen a case which had not yielded to a second and tighter application of Elastoplast."

As used in most hospitals for Varicose Ulcer, Varicose Veins, Sprains, Strains, Dislocations; after-treatment of Fractures, etc.

Elastoplast is the only Elastic Plaster Bandage with the correct degree of elasticity to ensure perfect compression and support.

Elastoplast

Patent No. 253,527.

BRITISH MADE.

The Elastoplast range also includes:—Special dressings for cuts, wounds, incisions, boils, vaccination, eyes, etc.

VISCOPASTE BANDAGES (UNNA PASTE TYPE).
A valuable adjunct to the after-treatment of Varicose Ulcer.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P.O. value 2/6 (Overseas postage extra) by the manufacturers:

An Address
ON
SOME RECENT POLICIES REGARDING PARTICULAR DISEASES

BY
SIR GEORGE BUCHANAN, C B , M D , F R C P
PRESIDENT OF THE PUBLIC HEALTH SECTION

From its earliest beginnings, organized public health has run general and special measures in harness However much action to secure the better general health and physical fitness of a population, and all that this implies, may signify, there are always diseases the prevalence of which is little affected by the possession of a high standard of general, or even individual, healthiness For them, special communal measures have to be devised in each case according to the nature of the disease and our knowledge of it, and these measures, perhaps more than any others in public health work, require periodically to be reviewed and modified as new facts are learnt or as new conditions of administration have to be reckoned with A few topical examples will not come amiss

PSITTACOSIS

My first topic, psittacosis, may seem a triviality, but it has a certain claim for notice It very rarely happens that the policy of complete exclusion of the introduction of a particular infection into a country can be attempted with success, especially in these days of rapid transit and in the case of a nation with external communications like our own We have adopted this policy for rabies, and to some extent for anthrax, and last year it was imposed as an emergency measure for psittacosis The emergency arose from the discovery of cases of this disease in various parts of the country, all associated with parrot infection, mostly by birds of comparatively recent importation coming to a large extent, though not wholly, through one channel or another from the South American countries—"Amazon parrots," as they were more or less correctly called Beginning with a few cases which one regarded merely as pathological and clinical curiosities, the number of people in England affected by this serious illness in a few months had exceeded 100, and at least 25 of these persons died There were instances in which human case to-case infection occurred without the intermediacy of the bird, and there were some striking examples of laboratory infection among those working at the pathology of the human and bird disease and trying to identify its virus

Meanwhile, many countries on the Continent had a similar experience, and concluded, before we did in England, that the importation of all birds of the parrot tribe had better be stopped They did this, since the period of infectivity seemed to be so indefinite and prolonged that no mere measure of temporary detention of the birds at the ports would meet the case, even if the necessary quarantine measures were administratively practicable The additional risk thus arose that England would become the dumping ground or new and possibly infectious parrots which could not be landed abroad at any European port The Parrots (Prohibition of Importation) Regulations were the inevitable outcome of these circumstances, and, with one or two exceptions possibly but not clearly traced to a breach of the order, they have been effective, and there has been no psittacosis in England since So far good, but no one can contemplate without dismay the indefinite deprivation of our population from the luxury of parrots Apart from their aesthetic qualities, they appear to create an intense domestic satisfaction, and it is their classical mission to supply material for anecdote

* Delivered in opening the Section of Public Health at the Annual Meeting of the British Medical Association Eastbourne 1931

But the difficulty of choosing the safe moment to let them in again is considerable, mainly owing to the difficulty of obtaining facts regarding the prevalence of psittacosis infection, particularly in South American countries, both among the wild birds and at the entrepôts and aviaries at the ports from which they are dispatched to Europe

It would certainly be desirable to have more evidence than we at present possess that the parrot infection of 1929 was only a passing and temporary epizootic It does seem fairly certain, however, that the birds frequently transfer infection from one to another after their captivity in the aviaries in which they are kept before sale and in the cages in which they are shipped, and that the mortality in course of these shipments is sometimes extremely high and almost certainly preventable One may commend in this respect such rules for healthy transport of birds as those enjoined by the Zoological Society—reprinted in Dr Scott and Dr Sturdee's report on Psittacosis to the Ministry of Health in 1930—which, if observed, should go far to reduce the risk Importers who wish to see a speedy revival of the parrot trade—which is said to be considerable and profitable—might do much to enlist public and official sympathy with their aims by themselves undertaking that all cause for criticisms on this score would be removed if importation were again allowed Such action on their part would, I feel sure, be welcomed also in other countries which are dealing with the same question The administrative inconvenience of separate action at the different European ports was made plain in 1929 30, and attention is now being given to the practicability at the next stage of common and simultaneous action at them all

YELLOW FEVER

The risks of virus research to laboratory workers, just referred to, have nowhere been so tragically illustrated as in recent work on yellow fever by deaths which entailed such losses to science as those of Adrian Stokes, Noguchi, W A Young, and Paul Lewis They have had an odd recent repercussion on public health policy in India, the Dutch East Indies, and elsewhere in the Far East, which is worth mentioning here Several Eastern countries have forbidden, or are about to forbid, the importation of yellow fever virus or material capable of carrying it, for any experimental purposes, even to laboratories of the highest repute Reactionary as this decision may appear, it has been initiated by the public health authorities themselves, on the ground that research must be sacrificed in view of the possibility of infection extending outside the laboratory and reaching the populations of vast regions in which yellow fever is unknown, but where its insect carrier, the *Aëdes ægypti*, is common

A more formidable risk of introducing yellow fever, by man or mosquito, into these populations has now also to be taken into account It may soon be possible to make relatively short voyages by air to those countries across Africa from the West Coast, where yellow fever is known to be endemic, and the countries which consider themselves threatened are not inclined to take chances Special attention to this position has been given in the draft international agreement for the prevention of spread of infectious diseases by aircraft, prepared last May by the Permanent Committee of the Office International d'Hygiene Publique Its policy is based, *inter alia*, on prescribing a minimum of action in the yellow fever affected countries sufficient to secure that no person is embarked on an air journey to the other countries concerned if there is risk that he has been exposed to yellow fever infection within six days On the face of it, this is a drastic requirement, but one which in present knowledge appears necessary in the interests alike of public health and of air navigation

Malaria

It is, however, rarely possible for the main line of policy directed against a particular disease to be one of national or international action for its exclusion. Public health policies are as a rule much more complex than that. The particular disease is there, and the collective action which ought to be taken about it does not admit of a single or simple formula. It depends on the nature and traditions of the community and its normal resources on the one hand, and the natural history of the disease on the other. To give another illustration from so-called tropical medicine, I would refer to the strides which, notwithstanding economic depression, have lately been made in many countries in combating malaria, the disease which, taking the world at large, probably causes more total sickness and invalidity than any other. Public health does not now offer a single policy based primarily on intensive local attack on the anopheline breeding place—successful as that method has been in limited areas specially favourable to its conduct, and impossible as it has proved as a practical proposition in most malaria-ridden regions. The modern method is to make a choice from several quite different policies according to the circumstances of the region. They have been made possible by a wholesome refusal to work on dogma, and by the practical application of the new knowledge acquired about malaria. Much of it, one may note, has come from the Horton Laboratory in this country, where special opportunities to study all phases of human malaria is afforded in course of the treatment of general paralysis by inducing malaria attacks. The latest work at Horton may well add another anti-malaria policy. It has not only shown scientifically that quinine, so powerful in its action on the malaria parasite in its vegetative, fever-producing form, has no power of arresting the development of the sporozoite which the mosquito inoculates with its bite. This was more than suspected before, on the evidence of the failure of quinine for malaria prophylaxis during the war. But now we have evidence that in this respect there are drugs which can do what quinine cannot, and that the temporary sojourn of a susceptible visitor to malarious areas may by their instrumentality be robbed of its danger.

I have just referred to the instance of yellow fever, in which medical requirements may put some obstacles in the way of aviation in some tropical countries. But if medicine is now going to make it possible for aviators to land in the far more numerous malaria-infested regions and be bitten with impunity, it will have made a very handsome compensation to the interests of air traffic.

In leprosy, too, a recent change of public health policy has lately been conspicuous; isolation of lepers is now being everywhere regarded like the isolation of the tuberculous, and not as an inevitable and fundamental necessity to prevent the spread of infection.

Isolation, Carriers, and Immunization

Coming nearer home in regard to infectious diseases, one may note, if not the adoption of new policies in place of those which have served us so long and on the whole so well, at least some new outlooks which are producing a considerable change in modern practice. Consider in this connexion isolation, carriers, and active immunization. Some six years ago I took part in an elaborate inquiry at the Ministry of Health into the effect of isolation hospitals on the spread of scarlet fever.[1] Most of the 30,000 beds in our isolation hospitals up and down England were then in use for that disease, and it is doubtful whether many of these hospitals would have been provided at all without faith in their necessity for scarlet fever prevention. With all the resources at our disposal we could only say in favour of the hospital isolation of scarlet fever that it represented a social convenience that no local area which has once possessed it would willingly dispense with, and that it usually offered facilities for treatment of the individual case not otherwise available. We could not say on any evidence that would stand examination that it has checked the spread of scarlet fever or that it has been responsible for its diminution in severity and mortality. This finding, come to rather reluctantly, confirms from practical experience the conceptions of scarlet fever infectivity and susceptibility which the immunologists have for some time been pressing on us from their side. To scarlet fever, in this connexion, we may add diphtheria; there is in both abundant justification of the isolation hospital as a place of treatment and a place of study, but much less as providing a principal method of preventing the spread of these diseases in the community. I will not enlarge on this matter save to draw attention to the repercussion of these conclusions on the modern use of the isolation hospital. The accent is shifted from isolation to hospital, and these special institutions require more than ever to be places which prove their medical advantage by supplying the most effective possible treatment, by saving life in the individual case, and by doing everything possible during the hospital treatment and by applying a following-up system to prevent the invalidity due to kidney and middle ear troubles and the like, which now forms the most serious part of the mischief done by these diseases. They afford, moreover, a means of clinical research on a large scale which is invaluable and cannot be elsewhere obtained; the testing of serum reactions of susceptibility to scarlet fever is a noteworthy example.

The same considerations have made it easier in recent years to extend the use of isolation hospitals to a variety of different diseases. The Metropolitan Asylums Board, now merged in the London County Council, found no difficulty in using parts of its infectious diseases hospitals when it desired to have units for dealing with the mental after-effects of encephalitis lethargica, and for the radiological treatment of cancer of the cervix. In the case of cerebro-spinal meningitis—to give one of many examples—the justification of the hospital by the facilities it gives for special treatment is particularly noteworthy. I would like to use this opportunity to plead in this connexion for full co-operation in the scheme now being put out at the Ministry of Health for collecting facts from all hospitals in the country, which will permit of the much-needed assessment of the curative value of different anti-meningococcus serums and of the different ways of administering them. In conclusion on this topic, I would not be thought to imply that the close association of isolation hospitals with bacteriological and clinical research is a new policy, but it is undoubtedly one which is coming into greater prominence and it is still full of promise.

Healthy Carriers

I have referred to bacteriological research rather than to bacteriological routine. With regard to the latter, there is a distinct tendency in infectious disease work to be critical of, or discontinue, what one may call the automatic use of bacteriological tests for the ascertainment of healthy carriers. It has now for some time been realized that carrier hunting adopted as an indispensable ritual in connexion with notified clinical diphtheria cases—with the object of the special treatment or segregation of the healthy carrier—may easily produce more embarrassment to administration and general inconvenience than is warranted by any advantages which it offers—*unless, of course,* in special circumstances under the fullest and most up-to-date laboratory control. Even more *is this* the case with

[1] Ministry of Health Reports on Public Health and Medical Subjects, No. 35, 1927.

the abundance of meningococcus carriers who can be found in connexion with the occurrence of cerebro-spinal meningitis; no one has seriously considered adopting the practice for the pneumococcus.

In the case of intestinal infections, I may note two recent examples suggesting the lengths to which one might be led by adopting the principle of treating all healthy carriers as a danger to the community. The first is the discovery during the last two Mecca pilgrimages that each time pilgrims returning by the quarantine station at El Tor have, on sampling, showed a material proportion of cholera vibrio carriers, some agglutinating according to ordinary standards, and this notwithstanding the fact that no clinical cholera was occurring among them or had occurred in any part of Arabia during the whole time of pilgrimage. The second is a recent experience of a paratyphoid outbreak due to milk in a district near London, where all known and notified cases were removed promptly to hospitals outside the district, which were on other sewerage systems. For eight weeks after it could be said that there was no known paratyphoid case in the district, it was possible at any time to find the implicated paratyphoid bacillus in the effluent from the sewage disposal works of that district. One does not know from how many temporary healthy carriers these bacilli came, but they must have been numerous and apparently did not spread infection in any case. One should perhaps add that although a general administrative policy for the routine hunting out of healthy carriers is now for good reasons less considered than was the case some years ago, it remains true that thorough concentrated search for carriers in particular cases, such as a food outbreak, may be essential for preventive work, and may be equally essential for particular epidemiological studies.

Active Immunization

The orientation towards the production of artificial immunity, which has resulted from the epidemiological and bacteriological studies of recent years, also must have some, if only passing, mention here. In this country it is too soon to speak of active immunization having been made the basis of a new public health policy, either nationally or locally, but there are tendencies in that direction. For diphtheria, systematic immunization is already an accepted policy in the case of the staffs of infectious diseases hospitals and in a few residential schools and institutions. As a systematic means of preventing diphtheria in the child community of a district, however, it has only been adopted here and there—so far with encouraging results—but on a scale far less extensive than in American cities. New York, which hitherto has had a diphtheria rate notably higher than that of any English city, claims that its immunization system, at present applied to some 300,000 children yearly, has brought incidence and mortality to a level below that of London. If immunization can be secured simply, with a minimum of inoculations (three separate inoculations seem too many for popular acceptance), without any material reaction, and without any danger—all postulates which seem capable of fulfilment—there seems no reason why systematic immunization against diphtheria, recommended to, and voluntarily accepted by, the population, should not before long become the main agency of diphtheria prevention in many areas. The same may be said for scarlet fever, though with less confidence until it can be shown that an immunizing agent is available which will do more than prevent the occurrence of uncomplicated scarlet fever, the mildness of which in these days makes it necessary to reckon with the argument that immunization is not worth while. If the anti-scarlet fever immunizing agent could be relied on to prevent the kidney and ear complications of scarlet fever, or if, still better, it could also afford a measure of protection against other diseases associated with the haemolytic streptococcus, the reasons to be advanced for its systematic use in a given community would be much stronger—again always supposing the same postulates as for diphtheria.

VACCINATION AND SMALL-POX

In this country a good deal of attention has lately been directed to the position of vaccination against small-pox our oldest example of successful immunization. Among the chief reasons for this have been the prevalence of small-pox of an apparently fixed low degree of virulence (variola minor); the Rolleston Committee's inquiries and recommendations, and especially in regard to the occurrence of post-vaccinal encephalitis; and the administrative questions arising in consequence of the transference of the administration of the Vaccination Acts to the major public health authorities. As this subject has been recently and fully discussed in a review issued in the Ministry of Health's public health series, I only make passing reference to it now. So far as methods of vaccinating are concerned, the recommendations of the Departmental Committee were in the direction of obtaining community protection against any variety of small-pox by repeated vaccinations in small dosage—for example, a single insertion of lymph, beginning in infancy. Meanwhile, the relative unimportance of variola minor as a cause of mortality or disfigurement on the one hand, and on the other the experience of post-vaccinal encephalitis, as a new though very rare risk to be reckoned with in the case of vaccination performed for the first time at school age or adolescence, have imposed a certain check on the policy of automatically advocating communal vaccination on an extensive scale when small-pox appears in a district. In the case of variola minor advocacy of vaccination is tending to be restricted to particular individuals at special risk.

This notwithstanding, it is well to remember that the necessity of applying our well-tried methods of controlling small-pox, including the use of vaccination, remains undiminished in the event of the importation or appearance of small-pox of the epidemiological type which was familiar to us in this country before the war, and is still so extensively prevalent in many parts of the world. It is worth noting, indeed, how very extensively mass vaccination of communities has recently been practised in countries which are affected with this major variety of small-pox. Following a small-pox epidemic period in 1919-21 the vaccination system of Italy was overhauled in 1923, so as to secure systematic vaccination of the population in infancy and at eight years of age, with a further vaccination for military service and in other circumstances. This has now resulted in over one and a half million vaccinations being performed annually in Italy. Each year at the Office International d'Hygiène Publique in Paris one gets surprisingly large figures from representatives of Eastern and tropical countries to illustrate the progress of mass vaccination—for example, in the French African colonies, in the Dutch East Indies, and in India. The Russian figures also are striking, it being claimed that now for some years more than eight million vaccinations have been yearly performed in the Union of Socialist Soviet Republics. So far as the customary variola major is concerned, this country is probably deriving benefit from these extensive mass vaccinations in other countries where that disease is endemic, seeing that the risks of its importation here are thereby diminished. One may refer in this connexion to the attention now given to the vaccination of passengers and crews embarking at Indian ports. This practice is becoming systematized not because of any specific requirement made on their arrival in the United Kingdom,

but because there are such requirements on their arrival in other countries. Proof of vaccination within more than 12 days and less than 3 years, attested by a certificate, is now being so much expected at ports over-seas that the ordinary passenger to the United Kingdom will find vaccination to his practical advantage during the voyage. When ships arriving from the East carry passengers the great majority of whom have been effectively protected, the introduction of major small-pox through the wholesale infection of passengers, as occurred in the case of the *Tuscania* in 1929, is unlikely to be experienced.

Cholera prophylaxis

Before leaving this subject, the very considerable part now played by anti-cholera inoculation in the epidemic work of Eastern countries may be mentioned. There can seldom have been a more intensive use of mass anti-cholera vaccination than when it was applied systematically to pilgrims before they attended the great Magh Mela at Allahabad in January of last year. At this ceremony it was reckoned that more than two millions out of three and a half millions of pilgrims bathed in the Ganges on the same day, and the risks of cholera infection from their ablutions can be well imagined. The actual cases of cholera treated were no more than 168, and no extension of the disease followed the festival. This was in striking contrast to the widespread scattering of infection which previous experience of these colossal gatherings had given reason to apprehend. General community inoculation against cholera is now habitually being practised in many parts of the East on the appearance of an epidemic, a recent example being the inoculation of more than half a million persons at Shanghai last year on the first appearance of cholera.

COMMUNAL DETECTION AND CONTROL OF DISEASE

I have given, perhaps, too much time to recent policies in connexion with certain infectious diseases, and am not attempting to-day to touch on others of at least equal importance, notably the special systems of control over tuberculosis and venereal diseases which have been developed so fully in this country, and on each of which there would be many interesting recent developments or adjustments to chronicle. I may pass to a few special diseases which in recent years have been made the subject of communal action in which the question of preventing case-to-case infection hardly arises, and where the public health object has been to systematize and organize the resources of an area by detecting the disease at its earlier stages, and also by securing that, at whatever stage it is detected, the sufferer receives the most effective treatment, curative or palliative, which circumstances permit.

Rheumatic Fever Policies

Let us take in this connexion the prevention of acute rheumatism in children, or its treatment when it occurs to prevent the occurrence of heart disease, of which there are well-known examples in London, and of which the work of the Invalid Children's Aid Association and that of the Home of Recovery for Rheumatic Children in Birmingham are also conspicuous examples. Local schemes for dealing with acute rheumatic infection in children imply three factors—ascertainment, supervision, and treatment. Ascertainment depends in the main on the School Medical Service, but is freely supplemented by the hospitals in the area and by other organizations. Experience in Birmingham and London shows that these means of bringing cases to light are effective. The addition of compulsory notification is being experimentally tried in three Metropolitan boroughs. After ascertainment, which is represented by a local "rheumatic register" of children needing attention, come the supervisory centre and institutional treatment. The rheumatism supervisory centre is worked in liaison with the School Medical Service, City Committees, the Invalid Children's Aid Association, and with the hospitals. Its functions are first those of exact diagnosis, then to arrange for appropriate treatment or regulation of school or home life, for continuous supervision to detect relapse, and instruction to parents and for scientific investigation. There are now some fifteen rheumatism centres in London, eight of these being at hospitals, and parallel work is being done in other parts of the country. The success of the rheumatism clinic and supervisory centre is bound up with the provision of institutional treatment. The scheme has to envisage not only hospital beds for acute cases, but prolonged convalescent treatment, consisting mainly of rest under good hygienic conditions, largely in the open air, followed by the most carefully graduated resumption of activity. It seems too soon to form an estimate of the number of convalescent heart beds necessary for a large city; the New York standard is stated to be 1 such bed for 10,000 population, a fifth of the beds being reserved for adults. Such a standard proportion is hardly at present of great consequence. An essential point of present local schemes is the possession of elasticity. The general requirements just outlined can be met by many methods according to the conditions of the area, so long as they secure the general medical co-operation necessary and the best utilization of the different agencies available.

Cancer Policies

Another illustration is afforded by local policies in regard to cancer. In this country deaths attributed to cancer form over 10 per cent. of the total deaths at all ages and 14 per cent. at ages over 50, and cancer death rates tend to increase rather than decrease. The question of communal action—whether by State and municipal effort or by organized voluntary effort, or both—has of late years received considerable attention in many countries. The establishment in France of twelve large provincial anti-cancer centres, with others in Paris, all supported by State contributions and based on the Fondation Curie, is an example, as is also the setting up of large cancer hospitals associated with research centres in Italy, Spain, and the United States. The British local policies to which I would like to direct attention represent something that is complementary to the work of our different cancer hospitals, new and old, to the investigatory work of our Imperial Cancer Research Fund, and to the various investigations facilitated by the British Empire Cancer Campaign. I refer to the attention recently directed to the question whether some of the larger public health authorities—county boroughs, notably those in relation with universities and medical schools, and possibly also county councils—ought not to utilize their own resources and their own special opportunities to organize the combating of cancer. The local policy means that in some suitable manner cancer cases that go to hospitals for treatment are regularly classified and their histories ascertained. Something must be done systematically to ensure that the local population receives, and at the proper time, the different forms of medical examination and treatment which are necessary. There is an educational policy in regard to pre-cancerous conditions. And, finally, in the case of operative or radiological treatment, the results are methodically assessed by means of observations of the patient continued over a number of years.

This kind of work can hardly be made at present the subject of a general national scheme. It wants local effort and local enthusiasm, and requires some definite local nucleus whose work will receive the encouragement and support of all the different agencies which directly or in-

directly may be concerned with cancer cases. This nucleus in one locality may be most conveniently based on the Public Health Department, but in another may best be executed through some hospital or voluntary association with which the Public Health Department co-operates. In respect of some kinds of cancer, particularly uterine, its nature may depend upon the extent to which the region is served by special departments or special hospitals at which radium treatment is given, and it results from this that local effort against cancer is now likely to be particularly active in connexion with those institutions to which supplies of radium have been allotted by the Radium Commission from the purchases of the Radium Trust. The kind of local action to which I refer in this summary way was lately reviewed rather fully in one of the memorandums (Cancer VII) of the Departmental Committee on Cancer at the Ministry of Health, the issue of which followed the transfer to the larger public health authorities of the many cases of cancer which were previously the responsibility of the Poor Law Institutions.

It has also been largely with the object of facilitating organized local action that the Departmental Committee has, over a series of years, recommended official circulars, and produced monographs on the causes and treatment of cancer of accessible sites. We owe to that Committee and its workers the determination of the average natural duration of the different varieties of cancer in different parts of the body, and various assessments of the extent to which appropriate operative treatment is being made use of, and facilities for early diagnosis are available. And its work has been specially useful when it has provided a reasoned judgement, obtained from home and from foreign sources, of the suitability of particular operative and radiological treatments, as judged by survival rates at defined intervals after those treatments. A city or region, therefore, which desires to consolidate its cancer work and settle a local cancer policy can, with the aid of these reports, start its work with some useful measures of the degree of achievement which can be reached by medical, surgical, and radiological skill.

The matters to be considered and co-ordinated at the local nucleus, which in general may be taken to be the Public Health Department, include the sufficiency of the local methods of securing that early and curable cases of cancer come to light at the right time and are treated in the right way. One is apt to forget how many different conditions are included under the name "cancer." Many of them, like cancer of the skin and lip, are so essentially curable that they only contribute a small proportion to cancer mortality. It is within the sphere of practical effort to bring cancer of the breast and cancer of the uterus into the same category. The local question is whether in fact these opportunities for cure are provided and used, and, if not, how the defect can be remedied through combined action of the local agencies available. There is again the large question of the sufficiency of palliative and nursing treatment in advanced cases of cancer, and, finally, the recording and following up of cases to which I have just referred. We can only wish well to those cities in which pioneer work is being done in these directions, not necessarily in the same way but always with the same object.

Conclusion

It seems, indeed, even from the random examples I have given, that in dealing with public health policies in regard to particular diseases we can hardly have enough local experiment. No one locality can attempt, or can be expected to attempt, to try out everything new that looks promising. But it is all to the good to find one particular area identifying itself, for example, with a carefully contrived effort to secure immunization against diphtheria, another specially concerning itself with a policy to prevent heart disease, or a third with cancer. The same applies to many other forms of local effort, none the less valuable because it arises from circumstances that are fortuitous, like a local experiment for the communal treatment of chronic rheumatism and fibrositis, or the establishment of a foot clinic. Always the existence of such particular policies gives life and individuality to the local health work, and particularly when that work is not confined to the statutory public health authorities, but, as in the instances I have given, requires a combined action with which the whole medical profession of the place is identified. The position is much the same with the international work for health which is becoming so important. Uniformity is often desirable, and standardization is often essential to progress. One requires standards for statistics, terminology and for all kinds of purposes of comparison and research. They are essential also to facilitate a common understanding between nations in those instances where success must depend on united effort. But this is something quite different from the view that one should aim at conducting national health work on standardized international patterns or in pursuance of authoritative international doctrines. Room must be left for each community to develop its health policy on individualistic lines according to its own resources and the circumstances and genius of its own population. It is a healthy sign of progress in public health that this process can continue side by side with necessary consolidation and standardizing, and that communities, large and small, should still be ready to work out and apply new policies of their own or to reconsider and recast lines of effort so consecrated by tradition that they usually are not questioned. By so doing they help the world at large, certainly by success if it comes, but often hardly less usefully by learning the lessons of failure if they should be disappointed—which, after all, has been the essence of progress in true art and science from the beginning.

LATE RESULTS OF OPERATIVE TREATMENT IN TOXIC GOITRE

BY

CHARLES S. D. DON, M.D., M.R.C.P.Lond.

ASSISTANT PHYSICIAN, SALFORD ROYAL HOSPITAL

The beneficial results of thyroidectomy in cases of toxic goitre have led to a steadily increasing number of these patients being referred to a surgeon for this operation, while the present pre-operative treatment with iodine has reduced considerably the mortality rate. There are comparatively few follow-up studies, but in the papers published the percentage of good results claimed has varied so widely that the average reader is left with the impression that, assuming the writer to be unbiased, either the criteria for judging results differ or the results depend on the clinic at which the operations took place; the former is probably correct. It seems probable that the average case operated on in the United States is milder than in England; this fact is no doubt the main reason for the difference in the immediate operative mortality rate. The apparent higher incidence of the disease in America cannot be due to earlier recognition by means of the more frequent examination of the basal metabolism, as, in my experience of 1,200 basal metabolic rate estimations in the past three and a half years, this test when properly done prevents many neurotic patients from receiving *x*-ray treatment. The test has to be repeated several times in these cases.

Follow-up Results of Various Observers

Before proceeding to give the details of my own cases I wish to mention the follow-up results of operative

treatment of toxic goitres obtained by other observers, but in doing so I make no attempt to include all papers on this subject; a selection of statistics has been made for the sake of comparing them with my own results. Many of these follow-up studies are based on correspondence, others on personal observations; in some the basal metabolic rate has been estimated, but very often this test has not been done. In 1920 Judd[1] found that of 100 cases of Graves's disease, 55 per cent. were cured, while of 100 toxic adenomas, 83 per cent. were cured. After the introduction of iodine the results improved, and Elliott[2] found that of 72 cases in which the basal metabolic rate was done at the time of the follow-up, 63 were considered satisfactory; out of a total of 100 cases examined then, however, 46 showed signs of definite visceral injury due to the disease or to the operation. Dunhill[3] states that of 185 patients about whom he received information, 167 were able to lead their normal lives, 4 died some time after operation, including 1 from high blood pressure. Walton[4] claimed that 55 per cent. of his cases were cured and that a further 26 per cent. were improved. Morley[5] assessed the results in 151 cases, regarding them as "very good" in 98 cases, and "good" in a further 37 cases. Smith, Clute, and Strieder[6] consider that 92 of 100 cases examined were cured, while Clarke and Black[7] report that of 64 cases in which basal metabolic rates were done at the follow-up, only 4 had a reading of over plus 20 per cent. Many of their cases were mild, 30 out of 62 having basal metabolic rates not exceeding plus 30 per cent. before operation. Thompson, Morris, and Thompson[8] state that of 190 cases followed up, 19.5 per cent. were not cured, and in their opinion the toxic symptoms seen in this group had, in most cases, persisted since operation; in 2 patients the symptoms subsided after operation, but recurred later. Crile[9] gives the number of his recurrences in cases of hyperthyroidism as 4.4 per cent.

A Follow-up of Forty-two Cases

In this contribution the details of 42 patients who were operated on either by Mr. G. Jefferson or by Mr. Garnett Wright are given, but before presenting details I wish to mention the method of examination.

A list of patients who had had operations for toxic goitre was compiled up to March 31st, 1930. These were circularized and asked to come into hospital for one night. A large number refused or did not reply. In many cases the information was volunteered that the patient was feeling quite well; all of these persons were excluded, but the 42 who accepted were admitted to the ward in the evening, a clinical examination, a basal metabolic rate estimation, an estimation of blood pressure, and an electrocardiographic examination being carried out on the following morning. The electrocardiographic results will form the subject of another paper, but at this point I may observe that an inverted T in Lead III was present in many of the follow-up cases. In some, myocardial damage present before operation was discovered to have cleared up completely at the follow-up; in others I had reason to believe that this had progressed since operation, in spite of an apparent complete relief of toxic manifestations as a result of operation. The other points to which particular attention was paid were the presence or absence of nervousness, tremor, exophthalmos, and the rate and rhythm of the pulse. Of these 42 patients, 38 were suffering from Graves's disease and 4 from toxic adenoma. In some cases, the basal metabolic rate was a little high compared with the pulse rate, but it was found that any untoward incident caused a surprising increase in the pulse rate (for example, the electrocardiographic proceedings), while the patient admitted that he was still nervous. A few patients had never had a basal metabolic rate estimation done before; for this reason I made them breathe into the Douglas bag and accustom themselves to it on the night of their admission, the test being done next morning. The basal metabolic rates were done by the Douglas bag and Haldane gas analysis apparatus. The average interval between operation and the follow-up examination was a little over three years, the longest interval being eight years, the shortest one year. The majority of these patients were women, there being only five men.

Results of Examination

The details of the examination of these patients were as follows:

Exophthalmos.—When present, this is one of the most outstanding features of the disease, yet in some cases where I had not seen the patient previously I found difficulty in deciding the previous degree; in these cases I accepted the patient's statement on the amount of improvement. Before operation, exophthalmos was present in 29 of the 42 cases; in 18 of these it was well marked, in 11 it was slight, and in the remaining 13 there was not any unusual prominence of the eyes. In some cases it is possible that another observer might have disagreed with my classification, but it will suffice to give an impression of the result of operative procedures on this sign. At the time of the follow-up examination, of the 18 cases in which it had been well marked it was absent in 5, much improved in 11, and in 2 there was no change, but, in these, toxic symptoms were still present, the basal metabolic rate being plus 20 per cent. and plus 31 per cent. respectively. Of the 11 cases which had shown, prior to operation, exophthalmos in a milder degree, it had disappeared in 4, but still persisted in a milder degree in 7 cases. In one patient (Case 7) the exophthalmos, which was well marked before operation, increased during the year, following a subtotal thyroidectomy, and at the present time (three years later) the exophthalmos is approximately similar in degree to that before the operation. This patient's basal metabolism was normal three weeks after operation, but each of four basal metabolisms estimated since have been about plus 20 per cent. I have not seen a case in which exophthalmos which was absent before operation has made its appearance since. Zimmermann[10] reports eight cases in which exophthalmos became more marked after a thyroidectomy had relieved the actual hyperthyroidism.

Nervousness and Tremor.—These were present to a greater or lesser degree in every case before operation, and were greatly improved in 39 of the 42 cases, though they were still present in 17 of these 39 patients. Of these 17 persons, 10 had basal metabolisms of or below plus 13 per cent., but in 7 it was still increased above plus 13 per cent. The remark made by Moschcowitz[11] might be applied to those cases with normal metabolisms yet still somewhat nervous: "Thyroidectomy therefore removes only the hyperthyroidism and the increase of basal metabolism; the personality of the constitution remains, a potential, given enough stimulus, to flare up into the more intense forms of Graves's syndrome." In the 3 cases in which there was no improvement, the basal metabolisms were still plus 47 per cent., plus 42 per cent., and plus 59 per cent. respectively.

The Blood Pressure.—Unfortunately there are very few of the cases in which a record has been made of the blood pressure before operation. This is all the more regrettable, as Clarke and Black[7] found that among those cases in which blood pressure readings were taken before operation and at the time of the follow-up, although the average systolic pressure had only risen 2 mm. Hg and the diastolic 9 mm. Hg, in certain cases the blood pressure had definitely increased. They mention that at the time

of discharge after operation 7 patients had a blood pressure of over 150 mm Hg while at the follow up 15 cases had blood pressures of over 150 mm Hg Among the cases I investigated, the blood pressure was taken on 35 patients at the time of the follow up, the average systolic pressure was 147 mm Hg and the average diastolic 88·3 mm Hg (the normal[17] for the average age, 36, is systolic 126 mm Hg, diastolic 90 mm Hg) If the patients are divided into two groups—namely, those above and those below 41 years of age—then the average systolic pressure for the group over 41 years is 153 mm Hg and the diastolic 89 mm Hg The average age was 45, and on that basis it should be systolic 129 mm Hg, diastolic 91 mm Hg For the group below 41 years the average systolic is 142 mm Hg and the diastolic 88 mm Hg, the average age was 28, and the normal reading for the age is systolic 122 mm Hg, diastolic 87 mm Hg Among these 35 cases there are 14 patients with a systolic blood pressure of 150 mm Hg or over, and of these 7 are below 41 years It seems clear, therefore, that the frequency of the increased blood pressure cannot be attributed to the age of the patient It was evident, also, that the height of the blood pressure had no relation to the number of years which had elapsed since thyroidectomy was performed It did not seem to bear any constant relation to the persistence of the toxicity As there are so few records of pre operative blood pressures, no further deductions can be drawn

The Weight —The successful operative treatment of this disease usually results in an increase in weight, the amount depending somewhat on the loss of weight which occurred before operation An accurate record of the weight before operation is only available in 27 cases, 23 have gained since their discharge from hospital, the amount varying from 2 lb to 48 lb, with an average of 16 lb Four patients have lost weight varying from 2 to 5 lb, 2 of these had normal metabolisms, and 2 have increased metabolic rates of plus 24 per cent and plus 25 per cent respectively

The Basal Metabolic Rate —The main purpose of this investigation was the estimation of the basal metabolic rate I regard this as the most important single piece of evidence in assessing the condition of the patient, errors may occur, not through inaccuracy in technique but because these patients are emotional, and any marked variation in the result as compared with previous readings, or any discrepancy between the apparent clinical condition of the patient and this test, must be viewed with suspicion and checked by a further metabolic rate estimation

Of the 42 cases described, a basal metabolic test was done before operation in 23 patients, in 17 of whom the rate was above plus 40 per cent Rates below plus 30 per cent were found in 4 patients, of whom 2 were adenoma cases, 1 was a recurrence and 1 (Case 38) was a case in which the rate was lower than was expected from the symptoms and signs The remaining patients were operated on before I began to do the basal metabolic rates These pre operative basal metabolic rates are mentioned in order to emphasize the fact that most of the 42 cases were of the type with well marked toxic signs, which, I believe, is operated on by surgeons in this country after medical treatment and in some cases x ray treatment, have proved inadequate The immediate effect of the operation was to cause a fall in the rate in 21 of the 23 cases, while in 2 (Cases 3 and 38) there was a rise In those cases in which the rate fell it did not necessarily approximate to normal at once, being at times below and at other times above normal limits The actual details are not given as the subject was discussed in an earlier contribution[18] The failure of the basal metabolic rate to become normal at once in many cases supports the view, re stated by Pemberton[14] that the surgeon cannot judge how much gland it is necessary to remove in order to bring the rate to normal and that the operation breaks a link in the chain of etiological factors which permits readjustment to normal in the physiology of the gland Of 7 patients who had had thyroidectomy and had later died of another disease, in 6 Pemberton found regressive changes in the histological structure of the gland, and this he regards as supporting his contention

At the time of the follow up a basal metabolism was done in all 42 cases, the longest time since operation was eight years, the shortest one year, with an average of just over three years These figures are presented in the accompanying table, and it will be seen that in 13 cases the rate is still above plus 13 per cent, a high

The Basal Metabolic Rates at the Follow up compared in some Cases with those taken before Operation

Case	B M R at the Follow up	B M R before Operation	Operation
1	Plus 25 %	—	Right lobectomy
2	Plus 7 %	Plus 38 %	Subtotal thyroidectomy
3	Plus 24 %	Plus 23 %	Right lobectomy
4	Plus 5 %	Plus 61 %	Subtotal thyroidectomy
5	Minus 5 %	—	Right lobectomy
6	Plus 19 %	—	Ligation of arteries
7	Plus 20 %	Plus 50 %	Subtotal thyroidectomy
8	Plus 5 %	Plus 51 %	Ditto
9	0	—	Ligation of arteries
10	Plus 13 %	Plus 60 %	Subtotal thyroidectomy
11	Minus 27 %	Plus 60 %	Ditto
12	Plus 6 %	—	Ditto
13	0	Plus 46 %	Ditto
14	0	—	Ditto
15	Plus 4 %	Plus 41 %	Ditto
16	Plus 25 %	—	Ditto
17	Minus 22 %	Plus 52 %	Ditto
18	0	Plus 61 %	Ditto
19	Plus 22 %	—	Ditto
20	Minus 7 %	Plus 27 %	Ditto
21	Plus 9 %	—	Ditto
22	Plus 3 %	Plus 57 %	Ditto
23	Plus 47 %	—	Right lobectomy
24	Plus 31 %	Plus 24 %	Subtotal thyroidectomy
25	0	Plus 64 %	Ditto
26	Plus 12 %	—	Ditto
27	Plus 5 %	Plus 47 %	Ditto
28	Minus 12 %	—	Ditto
29	Plus 42 %	—	Right lobectomy
30	Plus 8 %	—	Subtotal thyroidectomy
31	Plus 6 %	Plus 67 %	Right obectomy
32	Plus 2 %	—	Subtotal thyroidectomy
33	Minus 2 %	Plus 59 %	Ditto
34	Plus 59 %	—	Ditto
35	Plus 17 %	Plus 31 %	Left lobectomy
36	Plus 19 %	—	Right obectomy
37	Plus 24 %	—	Left lobectomy
38	Plus 7 %	Plus 14 %	Subtotal thyroidectomy
39	0	Plus 35 %	Ditto
40	Minus 15 %	Plus 64 %	Ditto
41	Minus 9 %	Plus 45 %	Ditto
42	Minus 1 %	—	Right lobectomy

percentage, but in 7 of these the operation consisted of the removal of one lobe; in 1 only the arteries were tied, while in the other 5 cases the operation was a subtotal thyroidectomy, and the persistence of toxic symptoms is surprising. In 2 of the lobectomies (Cases 3 and 35) the operation consisted of the removal of an adenoma from one lobe, but the persistence of toxic symptoms suggests that smaller adenomas are still present in the remaining lobe. The patient in Case 6 (the ligation) had auricular fibrillation with marked oedema and ascites. As she did not show sufficient improvement after ligation to warrant a thyroidectomy she was sent home. She had signs of cardiac failure for twelve months, after which she gradually improved, and at the time of writing (five years after operation) she has no oedema, and is carrying on a fair share of her household duties. The patient in Case 34 stated that her operation effected a complete cure, but the excitement of escaping out of her burning house caused an immediate recurrence; there is no enlargement of the thyroid. The other 4 patients with toxic symptoms who had subtotal thyroidectomies were considerably improved by the operation; the present toxicity is a persistence of symptoms and not a recurrence. In the remaining 29 cases the basal metabolic rate is within normal limits in 25, while in 4 it is below minus 10 per cent. Clarke and Black[7] found that 7 of their 64 patients had basal metabolic rates between minus 10 per cent. and minus 30 per cent. Smith, Clute, and Strieder[6] mention that in 19 of their 100 cases there was a basal metabolic rate below minus 10 per cent., while in 15 of these there was definite evidence of myxoedema; they attribute this to the pre-operative use of iodine. Of my 4 patients with a basal metabolic rate below minus 10 per cent., 2 showed definite evidence of myxoedema—namely, Nos. 11 and 40. The patient in Case 40 had a rate of minus 16 per cent., this in spite of 6 grains of dry thyroid daily. Immediately after operation her rate was minus 18 per cent.

There were 4 patients who still had auricular fibrillation. In 2 of these the pulse rate was over 100; in the third it was 68, and in the fourth it was 72. One of them, patient No. 34, has developed fibrillation since her operation, which was a subtotal thyroidectomy, but as the basal metabolic rate is at present plus 59 per cent. it is to be expected.

Conclusions

The disappearance of exophthalmos does not of necessity follow the complete relief of hyperthyroidism, yet a diminution of toxicity is usually followed by an improvement in this sign, which may disappear completely in cases which we regard as cured. Exophthalmos is likely to persist in those cases in which the metabolism has not dropped to within normal limits. Nervousness is invariably improved by a successful operation, but the patient may continue to be nervous in spite of a normal metabolic rate.

The majority of patients gain weight after operation, yet there are occasional cases in which an otherwise successful result is not accompanied by any increase, and this is seen even in a patient in whom there was a considerable loss of weight before operation. *Failure to gain* weight is occasionally associated with glycosuria, which is sometimes seen in Graves's disease, and may become more severe after operation.

Relief of hyperthyroidism and a lowering of the metabolic rate to normal limits usually follow a subtotal thyroidectomy; there are cases in which the metabolic rate remains above normal limits in which no increase of thyroid tissue can be made out, and in which no focus of sepsis can be discovered in any part of the body; worry and too little leisure are probably the factors which prevent a good result in these cases. Crile[9] attributes these failures to the presence of septic foci in other parts of the body, or to worry and overwork.

The removal of one lobe is followed by improvement, and patients Nos. 31, 36, and 42 were types with exophthalmic goitre in whom relief of hyperthyroidism has followed this operation. A satisfactory result has also followed ligation in two cases, and it will be readily understood that the improvement which ultimately followed was the cause of the complete operation not being undertaken at a later date. Ligation alone is not regarded as a curative measure, and while it is of interest to note that a normal metabolic rate can follow this simple procedure, it is probable that the operation had little effect on the ultimate outcome.

If the clinical condition of the 42 patients, their ability to do work, and the rhythm and rate of the pulse are considered in conjunction with the basal metabolic rate findings, the result of operative treatment has been good in 28 cases, improvement in 9, while in 5 the operation has been of little value.

I am indebted to Mr. G. Jefferson and to Mr. Garnett Wright for allowing me to examine these patients, and to Dr. G. Murray for some very useful criticisms.

TREATMENT OF CARCINOMA OF THE OESOPHAGUS*

BY

E. MUSGRAVE WOODMAN, F.R.C.S.

LECTURER ON DISEASES OF THE EAR AND THROAT, UNIVERSITY OF BIRMINGHAM; SURGEON EAR AND THROAT DEPARTMENT, GENERAL HOSPITAL, BIRMINGHAM

In this day of scientific progress we are faced with a disease, insidious in onset, slow in its development, relentless and remorseless in its course, and finally fatal in its issue. Against this disease we must admit that progress has been slow and almost unperceivable, and yet a great deal of work has been done, and many hopes have been raised only to be quickly dashed to the ground. With this admission we will first review briefly the principal difficulties, then proceed to a critical survey of the existing methods of treatment, and finally suggest certain points on which discussion would seem to be particularly valuable and indicate certain directions in which further research is urgently called for.

The principal difficulty lies in the anatomical formation of the oesophagus. Suspended at the entrance, where it is attached to the back of the cricoid cartilage, and fixed at the lower end, where it traverses the diaphragm, it remains completely mobile in the centre. This can be demonstrated by passing a tube into the oesophagus and viewing it on the *x*-ray screen, when the end of the tube can be freely moved from side to side.

In the cervical region the gullet lies in intimate contact with the trachea, into which perforation readily takes place. In the central zone the left bronchus is easily

* Read in opening a discussion in the Section of Otology, Rhinology and Laryngology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

invaded. In the lower mediastinum the pleura is wrapped round the tube in an all too close embrace, and damage or infiltration very readily takes place; while in the diaphragmatic region the vascular and lymphatic anastomosis is so free that the condition is hopeless from the outset. Except in the neck, the gullet lies deep among sensitive and vital structures, and external operations have not achieved success. The absence of a peritoneal coat is of vital importance. Such a coat, if present, would delay extension and give rise to adhesions which would be of invaluable assistance in treatment by diathermy.

Little is written in the textbooks of anatomy on the lymphatics of the oesophagus. Three years ago I had some injection experiments carried out for me. The submucosae of numerous gullets were injected with methylene blue and silver nitrate. Great difficulty was met with in inducing injection, and finally a specimen was produced which showed the finely developed reticulum of the oesophageal lymphatics.

Experiments were carried out by injection into the wall of the oesophagus of monkeys, to show the distribution of the normal lymphatics.[1] The animals were killed twelve days later, and the lymphatic areas draining from the oesophagus were found to be injected with methylene blue. The most widespread diffusion was found, including the glands at the base of the neck, and the mediastinal and intercostal glands. A remarkable extension took place on to the parietal surface of the pleura and the pleural surface of the diaphragm. The inference from these experiments is that lymphatic spread in the early stages is slow and takes place with difficulty, but when once this fine reticulum has been broken through the invasion is widespread and comparatively rapid.

TREATMENT BY DIATHERMY

Diathermy was ushered in with considerable promise, but has been largely abandoned. We have here an instrument capable of complete destruction of the localized growth, but it has to be used with great care, or fatal operative results take place. To eradicate an oesophageal growth with safety by diathermy it is necessary to raise up a protective connective tissue reaction, analogous to callus formation, outside the growth. There was hope that by repeated small applications of diathermy success would be attained in the human subject. The expectation has not been realized.

In 1926 I carried out some experiments on rabbits and monkeys with a view to stimulating connective tissue reaction around a localized area of the oesophagus. Various irritants, such as silica and iodine, were injected through the walls of the gullet in the living monkey—without effect. A large quantity of solid paraffin was introduced into the mediastinum through the oesophageal wall by a specially constructed syringe, and on the death of the monkey ten days later not a trace of paraffin or any resulting reaction was discovered. Lastly, the trans-mural passage of electric currents was tried, but no irritation of the surrounding tissue took place.

Treatment by diathermy is a painless operation, which has as its result dilatation of the lumen of the gullet and increased ease of feeding. It is not without danger, and several patients died within a day or two of the operation from fatal leakage into the pleural cavity. As a curative means it has proved a complete failure for the reasons given above. As an operation of palliation it is of distinct value.

RADIUM TREATMENT

Radium treatment has now almost entirely replaced diathermy in the treatment of carcinoma of the oesophagus.

External Application.—It is remarkable how few cases of carcinoma of the oesophagus within the region of the neck present themselves for examination and treatment. Of those limited number of cases a large proportion consist of that peculiarly difficult growth which takes place within the sphincter at the entrance to the oesophagus and behind the cricoid. In general it may be said that if the growth can be reached from the neck my experience is altogether in favour of excising it if in any way possible. The external application of radium has not proved of much value in my hands in this area. The external approach by a trans-pleural thoracotomy is a severe operation, and in the majority of patients their general condition and lowered vitality render them unsuitable for this procedure, and during the last year we have not had a single case. During the previous two years three patients were treated jointly with Mr. Seymour Barling; all three died within a month for various reasons. The great drawback of the external approach to the oesophagus with a view to implanting radium is that any such treatment would of necessity have to be repeated.

Interstitial Application of Radon.—This method the author introduced in 1928.[2] By this means radium emanation is carried into the substance of the growth. The technique is fairly simple. The growth is treated by adrenaline before operation; the position of the lumen is ascertained, and if necessary it is dilated. The radon seeds are inserted by a special trocar and cannula, fitted on to a handle and made by Messrs. Mayer and Phelps. The seeds are buried deeply into the upper part of the growth; their number and position are checked by *x*-ray examination on the following day, at the end of a week, and at the end of a month. The disadvantage is that only the upper part of the growth can be dealt with at the first operation, leaving the lower part to be dealt with at a subsequent insertion. Experience is that the effect of the radon is to cause shrinkage and devascularization of the growth, and in two cases the growth has apparently disappeared entirely.

Central Application of Radium.—In this method the growth is dealt with from the centre of the lumen, which is dilated and a more or less rigid tube inserted, to the outer surface of which radium needles are fixed. It has the advantage of definitely dilating the lumen. It has the disadvantage of dealing with the growth from the centre and most degenerated part, and one which is farthest from the active and growing edge. In addition, sepsis on the ulcerated surface is encouraged by the advent of radium. For treatment by this method I should like to introduce two new tubes. The first is a rigid metal tube with grooves in a direction parallel to its length, and the second of hard rubber of similar shape. The rubber tube is the one now in use, and it has two advantages over the rigid metal tube: (1) When the patient is moved back to bed or sits up there is no danger of rupture of the oesophageal wall; (2) there is no secondary radiation from the surface of a metal tube. After insertion the patient should be *x*-rayed to ascertain the position of the radium. The value of an *x*-ray examination is well shown by the following case:

Male, aged 56. The growth was 14in. from the teeth. A rubber tube containing six 5 milligram tubes of radium screened by 0.5 mm. platinum, was inserted, and the string was suitably fixed by plaster behind the ear. On the fourth day he gave a violent gulp and swallowed everything, including the strings and strapping. He was *x*-rayed and the tube was seen on the right-hand side of the abdomen about half-way down, and it remained in this position despite the use of purgatives. On the fifth day it was removed by laparotomy, and the radium was found in the duodenum and the strings were trapped in the stomach.

A review of the treatment of cancer of the oesophagus would not be complete without a mention of the operation of gastrostomy. From the endoscopical point of view I

regard the necessity for this operation as an expression of complete failure. Such a failure will from time to time occur in every surgeon's hands, but I have never known a patient who was grateful for having had the operation carried out, nor can I recall a case in which subsequent endo-oesophageal treatment by radium, etc., was rendered easier or more satisfactory.

The proper use of diathermy, notwithstanding that it fails to cure, will in the great majority of cases maintain the patency of the lumen sufficiently for the patient to maintain fluid nourishment. However carried out, the shock produced by gastrostomy absorbs a large amount of the patient's available strength and vitality, a deep cloud of depression settles on him, and he ceases to care enough to live.

Points for Discussion and Inquiry

I now propose to indicate some points which seem to call for discussion and to require further research. I will enumerate them as follows:

1. *Diathermy.*—Is it possible to increase the safety and efficiency of the use of diathermy in the oesophagus by stimulation of a protective peri-cancerous infiltration or by any other means?

2. *Radium.*—Should mural or central methods of implantation be adopted—or a combination of both? What variation in the technique can be adopted, such as (*a*) dosage in total milligram hours, either by reducing the radium content per needle or increasing the length of exposure, or the reverse process; (*b*) screenage—increase of thickness of platinum or other metal?

3. *Fluorescein.*—What is the influence of fluorescein, if any? Are there any substances of a similar nature more effective?

4. *Radio-sensitiveness.*—What types of tumour are more radio-sensitive, and why? Can radio-sensitivity be increased? There can be no question that some tumours of the oesophagus appear to be very radio-sensitive and others to be entirely unaffected. Why is this?

Consideration of the methods of treatment of carcinoma of the oesophagus available at the present time inspires *no great hope for the immediate future*, but despondency is to be deprecated. Consider the triumphs of radium over cancer of the mouth, and how little we know yet of the variations in the technique required for different areas. When we glance back along the long corridor of time and review the successive triumphs of surgery we can but feel that this, the most difficult of all growths to eradicate, will yet yield to patience, hard work, and clear thinking. May it be so.

POST-MORTEMS: THEIR OBJECT AND PERFORMANCE*

BY

EDWARD F. HOARE, M.D.

BARRISTER-AT-LAW, H.M. CORONER FOR THE LEWES DISTRICT OF EAST SUSSEX

In this matter there is a natural bias on the general practitioner's part to resent the snatching from him of another portion of what has been pessimistically described as "all that is left to him" in an age of specialization. As a G.P. for over 20 years I sympathize with this attitude, and I feel somewhat of a "Judas" should I appear to be on the other side; and yet, perhaps just because of this instinctive general-practitioner prejudice which only reluctantly yielded to knowledge and experience, I hope my remarks may be regarded as adverse rather than hostile. Judging from the correspondence which appeared in the *British Medical Journal* in August, 1930, by "Rusticus" and others in later numbers, and from my own experience, the wish to do post-mortem examinations is often more a theoretical protest than a practical desire. I have been begged by practitioners not to give them this work. Others do them as "a messy job," not so much for the fee but as a protest at being deprived of the work and its fee. A few are eager for the w[illegible] all three groups invariably preface their exa[illegible] Vesti[illegible] every pregnant remark, namely, "It's se[illegible]gists naturally fe[illegible] is their work, and, in fact did a p.m."

[illegible] of work usually involves not con[illegible]cts tice and the frequent examination living and dead, this seems a logical examination of the The fact that a pathologist is *ipso fa*[illegible]thologist's scope competitive practitioner must, financially, than compensate the general practitioner for others in practhan compensate the general practitioner fo[illegible]es in the fee he loses by the pathologist taking this wo[illegible]ion.

* Read in opening a discussion in the Section of Pathology and Biochemistry at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

[illegible]se cases. Crile Associa-

But two even more vital points are involved. One is the loss of experience in pathological conditions to the general practitioner if post-mortems become a pathologist's perquisite, and the other is the similar educational loss to the pathologist, after specially training himself and simultaneously limiting his financial field, if post-mortems are scattered among various individuals.

The "acid test" of interest in knowledge is the gaining of experience without fee. The individual loss to each practitioner is a small price to pay for the removal of a potential rival, and he can better retain and improve his pathological knowledge by watching a trained man deal with morbid organs than by handling them himself—and here "Rusticus" agrees with me. Some practitioners are eager lookers-on at their patients' post-mortems. Others have received suggestions to be present with an acidity which left no doubt as to the chemical reaction of the test, nor of the "psychological content" of their interest. Personally I realize that there is a monetary loss of time involved in merely attending a post-mortem, and I could wish a further fee were payable for such attendance, or possibly (though not probably) the pathologist might agree to apportion part of his fee to the attender who might really prove a valuable attendant.

Complexes—Lay and Medical

As to the "complexes" of this subject. They are varied and numerous. First—and, let it not be forgotten, our master in the long run—is "the man in the street." He is composed of several groups. The "home is my castle" group, who object most strongly to the whole business; think it "a lot of darned doctors' nonsense and a fee-making dodge"; "won't have any of mine cut up"; and, to do them justice, won't give in till a Coroner's Order, a police-sergeant, and three men actually remove the body from the house. Then there is a large group, and one has nothing but respect and sympathy for them, who are genuinely horrified, and if it must be done beg "Can't our own doctor do it, in the scullery?" regardless of the fact that ten or fifteen summers may have passed away since their own doctor did a post-mortem, and that the average scullery is hardly a desirable place—as Dr. Webber agrees,

though Dr Gibson expresses a preference for the farm kitchen table (*British Medical Journal*, September 20th, 1930) Another, and increasing, group like it "cleared out of the house and done by someone who can do it properly" and lastly, as a sign of the times perhaps, I have had a juryman ask, "You've done a lot of post mortem examinations I suppose, doctor?"

Secondly, there are medical complexes These, as usual, surpass all others in complexity They are composed of self interest, high ethical considerations, etiquette, illogicalness, stupidity even, combined with intelligence, decent feeling, and practical common sense, the whole producing in my legal brethren's minds the kaleidoscopic effect of being hit on the back of the head by a charabanc

There is the general practitioner who loathes post mortems, referred to by "Urbanus" in the *British Medical Journal*, September 27th, 1930 There is the one, like Dr Gibson in his letter of September 20th, 1930, who sees "no reason why any G P should face a post mortem examination with any more apprehension" than any other part of his daily work There is the one who, deciding beforehand the cause of death, confirms—with what he considers an open mind, but with the brain of the cadaver unopened—his diagnosis There is the 'de luxe" operator He needs marble fittings, hot and cold water laid on, an assistant, a clerk, and chromium plated instruments, failing any of these he is apt to leave the body in such a state that the undertaker complains to the coroner, and only with difficulty is a public scandal avoided As his opposite is the good fellow, who does the best he can, and a very good best it is—often done in a reeking stable by lantern light, a tub of frozen water to wash the parts in, the local constable or the village idiot his only assistant—and yet everything is left decently and in order, and, astonishing as it is, the cause of death is found Then there is the embarrassing man who has the enormous moral courage to state on oath, after a long and conscientious examination, that he can find no cause of death, thereby compelling a bemused coroner to fall back on the blessed words, "death from natural causes," as described by 'Rusticus' and Dr Binns in the *British Medical Journal* September 13th, 1930 Again, there are the "whole time service hoggers" with the plan of a whole time pathologist for a large area, and virulently opposed to them is the "every practitioner his own pathologist" school

Lastly, there is the coroner complex This official has been described by Dr Jones on September 27th as "a survival from early middle ages," "obsolete," "a hopeless official," "the butt of the satirical", and the medical coroner who has ventured to be called to the Bar is dismissed as "amphibious" which has an unpleasantly reptilian and prehistoric sound This however, is only a kindly way of expressing the apparent detestation, contempt, and hostility with which this *bête noire* is regarded by the medical profession Personally, I and many other coroners have come to see that this hostility is more apparent than real, but I do in all seriousness suggest that the medical profession for its part, should realize that coroners are more often than not their best friends, and that a post mortem report or an inquest often vindicates the doctor in public esteem The child like shyness of publicity, so inherent a part of the practitioner's make up, has often a wrong construction put on it by the public Since mixing more with laymen I have realized that doctors are often over touchy about trifles, and not quick enough to come out into the open to safeguard their vital interests In my opinion the best 'resolution' of this "complex" in general is for more doctors to apply and qualify for coronerships as I am convinced that its true cause is the deep professional resentment at a layman "butting in" on medical matters and for the most part the coroner's office is a medical affair and tending to be more and more so

STATISTICS

I do not know the number of post mortems performed (with the consent of relatives) in private practice, in hospitals, and in mental hospitals, but it must be large, as almost all mental hospitals invariably hold post mortems, and these deaths alone amount to 12,564 a year for England and Wales These examinations are not official ones, but purely of a private medical character, and they are done for the most part by skilled pathologists attached to institutions

It must be understood that the coroner can only direct a post mortem in suspected cases of sudden, violent, or unnatural death There must be reasonable ground to suspect, he cannot hold either post mortem or inquest merely at his will The total number of deaths reported to the coroners on these grounds in 1929 was 67,259, resulting in 32,612 inquests, for which 11,468 post mortems were held, and 34 647 inquiries resulting in 7,906 post-mortems giving a total of 19,374 post mortems a year So, roughly, a post mortem was held in less than every third inquest Of the inquiries, 12,564 were into the deaths of mental patients upon whom private post mortems had been performed, and there were 280 official post mortems This leaves some 22,083 inquiries, with 7,906 post mortems, again approximately one post mortem in less than every third inquiry These figures are from the *Criminal Statistics* for 1929, since then the accident fatality rate has increased so the figure chiefly relevant to this discussion is some 20,000 post mortems directed by coroners

THE CORONER'S DUTIES

In this connexion the question at once arises "Whom may the coroner direct?" The Act of 1926 leaves untouched his power under the Act of 1887 to *summon* "any legally qualified medical practitioner who attended the deceased at his death or during his last illness' or, if not so attended, 'any legally qualified medical practitioner who is at the time in actual practice in or near the place where the death happened' But the newer Act in Section 21 adds, "He may further *request* any other legally qualified medical practitioner to make a post mortem examination and report"—"other" here means one not in actual practice in or near the place Now the whole of this Section relates to sudden deaths where a post mortem may prove an inquest unnecessary The compellability depends on practice in the place, but to neither person can the coroner pay more than the statutory fee of two or three guineas (which is not by the way, one and a half guineas, as quoted by Dr Wilks in his letter published in the *British Medical Journal* of September 13th, 1930) Section 22 of the 1926 Act deals with cases after an inquest has been decided on Here again the directing can only apply to those practising in the place, but specially qualified persons (medical or otherwise) may be requested to make a "special examination' and these persons can be paid a special fee, but sanction to incur the same must be first authorized by the county council These sections affect a pathologist in the following way If deemed to be in actual practice in the place he is a compellable witness at the statutory fees If deemed not to be in actual practice he is not compellable but can only be paid the statutory fee in cases of post mortems to avoid inquests If however, he is asked to go elsewhere he can refuse or if he accepts he can be paid a special fee under Section 22 This Section therefore has a very direct bearing on the feasibility of employing a pathologist for every post mortem in a county His fee would have to be agreed

on every time—unless he accepted the statutory fees—and in any case he could always refuse to act.

The next query is, "When is a post-mortem to be held?" and the answer is, "When the coroner may direct." He is not bound to call in any medical opinion, and, indeed, often the direct evidence of facts is better than medical opinion, and the statistics plainly show that coroners thought post-mortems necessary in only approximately a third of all deaths reported to them. This should pacify those who, like Dr. Gibson in his letter of September 20th, complain of unneeded post-mortems. In the remaining two-thirds the evidence of medical witnesses, medical reports, and self-evident facts satisfied the coroner—that is, satisfied him in a legal sense as to how the deceased came by his death. But to be satisfied as to the actual medical cause of death, confirmed by post-mortem examination—and this alone can make certain of any diagnosis—would have necessitated 21,114 more examinations in inquest cases, at a cost of £66,504, and 14,177 more examinations in injury cases, at a cost of £29,771, thereby adding a further cost of £96,280 to the present total expense of £122,525. In my area alone the cost would have been £750, exactly doubling my present total annual expenses. This gives a complete answer to those enthusiasts who consider that the coroner's office should be a pathological "annexe" for the use of the profession instead of restricting itself as to the manner how the death occurred and whether or not it was criminal in character. It may also explain the hesitancy of some appointing bodies to make medical coroners—once appointed their discretion in disbursing lawful expenses is beyond control; the legal coroner may well appear safer to those who pay the bill!

With the public, for the most part, dreading post-mortems; with the accommodation often a disgrace to the vaunted humanity of the twentieth century; with the doctrine that every practitioner was the equal of his fellows, and all fully capable of doing post-mortems, thrust on me by some; and that no one except a trained pathologist was of the slightest use urged on me by others (not, by the way, by the pathologists themselves!); told by some that finding the precise cause of death was the scientific way, and by others that post-mortems were of little use and very costly, that I mustn't pander to the profession, and that, on the other hand, it was a mistake to alienate my professional brethren—is it surprising that I did a very foolish thing when first appointed coroner? I asked for advice from an authoritative medical body. My only justification for this is that I didn't accept it when it arrived!

It may possibly interest the meeting if, without appearing egotistical, I mention the attitude I adopted in regard to post-mortems in this area. I found a district of some 1,000 square miles full of strange doctors, and a legal deputy coroner who, quite properly, was accepting the legal fiction (so aptly expressed by "Rusticus" in the *British Medical Journal* of September 13th) that every practitioner was of equal skill in the eyes of the law. To some extent modifying this doctrine was an idea that post-mortem fees were the perquisite of the police surgeons, and occasionally a vague person known as a pathologist was engaged. With so many conflicting ideas it appeared to me that two essentials had escaped attention—the public interest and the efficiency of the work.

It is in the public interest that the distressing finale of a post-mortem should be performed quickly and under as decent circumstances as possible. The disgusting circumstances of the police hawking round a body, and then at length finding a resting place in an old barn or, in one instance, a public bakery, will only cease when public authorities, instead of shifting the blame from shoulder to shoulder, get together and do something to make England a land fit, at least, to die in. Meanwhile the risk of such scandals has been lessened by the public-spirited action of the mental hospitals' committees in allowing me to remove to their mortuaries bodies for post-mortem examination by their own pathologists. The public is thereby served and the efficiency of the work done gives the county value for money paid out. This system might well be adopted by local hospitals and union infirmaries, apart from their own dead. There is no need for the provision of costly mortuaries anywhere within 5 miles of such a hospital; all that is required is an improvement of existing facilities, which in part would be covered as regards cost by the sums payable by the coroner for such accommodation.

Beyond the reach of hospital centres, there remain villages, and though these lack anything that can be described as suitable mortuary accommodation, they do possess a police surgeon. Now though one can never concur in the idea that post-mortem fees are part of a police surgeon's emoluments, yet the employment of these officers for this work has points in its favour. He is the doctor most likely to see first those cases which will be reportable to the coroner—such as suicides, wounding cases, road fatalities, sudden deaths—and if he likes this work he does appear a suitable alternative to the pathologist. Virtually, this is the "modified specialization" advocated by Dr. Collier on September 27th. Further, by giving the rural police surgeon the four or five cases occurring in his area annually, his experience is kept up, and it is more in the public interest that one man should get four or five fees as the price of his efficiency, than that four or five practitioners should get one post-mortem every two or three years.

Then there are the scattered hamlets, with only a shed or cowhouse by way of shelter. These present considerable difficulties. The charge for removal of a body to a more suitable place is a heavy one and even the doctor's mileage fee is an item. Certain it is that his is the only skill available, and, as I have said, his results and work are a feather in our profession's cap; but here one finds after a while that by force of geographical circumstances he does all the post-mortems "round about here" and so he is virtually a specialist.

Lastly, there are the big towns. Here there are most things that the soul, or what corresponds to it, of a pathologist can desire—light, warmth, hot water, proper tables, instruments, and proper and decent means of conveyance to and from the mortuary. Here the only question is, "Who is the best man for the job?" In this connexion I have recently received from the British College of Nurses a resolution urging the employment of female attendants, preferably nurses, for the handling of the female dead. This principle is a sound one, and would, I am sure, do much to assuage the feelings of the relatives; some day I trust it may mature, but just now the need for mortuary accommodation appears the more pressing matter.

The Purpose of a Necropsy

For what purpose is a post-mortem examination held? The obvious reply would seem to be, to ascertain the cause of death. This is, however, only the medical point of view, and it is just because this function of a post-mortem bulks so large on the practitioner's horizon that his observations often fail to be of substantial use, and until he visualizes a post-mortem as a public service, rather than a satisfaction of medical curiosity, this will continue.

Of the 20,000 cases under consideration, I do not suppose the coroners were the least interested in the cause of death, except in so far as it threw light on the question

of "How the deceased came by his death." Until it is realized that the medical interest lies in the pathological cause of death, whereas the legal interest lies in the manner how death came about, there will be conflict and misunderstanding between doctors and coroners. The cause and the "manner how" are of course correlated, but they are not one and the same thing. The finding, for example, of an inflamed intestine as a possible cause does not eliminate other possible causes, and moreover, without further critical examination, no light is shed on the one and only question interesting the coroner, namely, was the condition due to disease, external injury, or suicidal poisoning? Similarly, disease of the heart may suggest a cause of death. But without examination of the brain or kidney how is a granular kidney or cerebral haemorrhage to be excluded as a cause? And if the latter were a cause, the manner of its origin, whether by disease, accident, or assault, would at once arise. Yet frequently the brain is never examined, if a possible prior cause is found.

Again, minor points, not in themselves a cause of death, may indicate much as to the "manner how"—for instance, atrophy of one eye may be of enormous consequence in a motor fatality inquest; a perforated ear-drum or an otitis may throw light on many a suicide case. Signs of muscular atrophy or arterio-sclerosis may convert an apparent suicide into an obviously accidental death and make a vast difference financially to the relatives. The presence of heart disease in one found dead, with injuries from falling, at the foot of a haystack will raise intricate questions as to whether he fell dead of heart disease, and so died from natural causes, or whether his injuries caused or accelerated his death, making it accidental. Simple points like the wearing of dentures having a missing toe, whether hair is dyed or not, may be the only evidence of identification or age. Then there are the questions of "live-birth" and "stillborn," the cause of death in newborn infants and the innumerable points in favour of wounds being homicidal, suicidal, or accidental. All or any of these cases may involve attendance at the higher courts where the cleverest brains will be pitted against the post-mortem operator. I mention a few of these cases within my own experience to stress the legal as well as the medical aspect of post-mortems and to encourage medical witnesses to suffer "the fool of a coroner," if not gladly at least with patience, bearing in mind that the seemingly foolish questions put to them are with a view to ascertaining not only the cause of death but the truth, the whole truth, and nothing but the truth.

WHO SHOULD MAKE THE EXAMINATION?

We are now, I trust, in a position to consider who is best fitted to undertake a post-mortem examination.

First, let it be understood that every county and borough has its peculiar difficulties and that the ideal cannot, in this working world, always be attained. My own scheme of pathologists where possible, police surgeons as an alternative, and odd practitioners in odd corners, has objections. In the first place the mileage fee of the pathologist, even if he consents to go out of his area, adds considerably to the expense, and in most cases he will demand the special fee under schedule in place of the statutory one. In the second place local practitioners are sometimes bitter and resentful of the local police surgeon doing post-mortems on their patients, though in parenthesis I may say that I consider, legally, it is not desirable for anyone to do a post-mortem on his own dead patient —not even a police surgeon—because an unbiased outside doctor's opinion will carry more weight with the coroner's jury and in any subsequent court proceedings. In the third place, the odd doctor doing his odd post-mortem is put to an infinity of inconvenience, trouble, and disagreeableness out of all proportion to his occasional fee.

Personally I hope in time to concentrate more and more at hospitals and mental hospitals, but I quite frankly admit that if opportunity arose to employ one pathologist for all cases I should welcome it. Unless post-mortems were increased on medical grounds only—that is, by some 200 a year—a whole-time "jurisconsult" could not be kept employed. This was one of the suggestions made by Dr. Mahomed in the *British Medical Journal* of September 13th, 1930. But the present total fees for these examinations would constitute a fair additional emolument, for about some two cases a week, for a part-time pathologist.

I submit to the meeting that this work is peculiarly that for a skilled and trained pathologist, on the following grounds:

(1) That the legal fiction of the equality of practitioners applies only to legal status and their *potential* abilities. Their particular superiority in any branch depends on opportunity and experience, and only implies a particular and not a general superiority. I maintain that a trained pathologist is superior to either a surgical or medical consultant or to a general practitioner for this particular work.

(2) That the legal aspect and the intricate points involving the Workmen's Compensation Act and general insurance are more fully grasped by constant practice, and, in the event of High Court actions, pathologists are more likely to be regarded as "experts" and their opinions acceptable as "evidence"; for, to elevate his *opinion* into *evidence*, the witness must show special skill and experience, as remarked by Dr. Jones in the *British Medical Journal* of September 27th, 1930, and as "experts" they will stand up better to cross-examination, as stressed by Dr. Mahomed on September 13th.

(3) That the extended powers under the Coroners Act of 1926 to hold post-mortem—without subsequent inquest—throw a great responsibility on the coroner; he relies entirely on the post-mortem report, which is not evidence on oath, and which it is essential therefore shall be accurate, informing and absolutely reliable in every detail. In this connexion I should like to refer to Coroner Ingleby Oddie's appreciation of the services of the late Dr. Weir, pathologist to the National Hospital for Diseases of the Heart, in the *British Medical Journal* of May 16th, 1931.

(4) That the handling and the correct interpretation of morbid changes and the actual performance of the post-mortem itself can only be acquired by training and retained by constant practice, and there are insufficient cases to give this opportunity to all.

(5) That the transference of this branch of medicine to pathologists encourages pathological research and is a just and equitable return for these specialists forgoing the financial rewards of the practice of surgery or medicine.

(6) That by this specialism the efficiency of the work done is increased and the public better served thereby.

If I have seemed to talk too much of the general problems of this subject it was only done that you might, if my experience could help you, see it from as many sides as possible and so come to a reasoned judgement. Some of you may heartily disagree with me, but I trust that none will doubt the sincerity of my convictions, which arise from a single desire—that the profession shall be an even more perfect instrument for the public good.

PUBLIC HEALTH PROBLEMS ATTENDANT ON AIR TRAVEL*

BY

A. MASSEY, M D , D.P.H

MEDICAL OFFICER OF HEALTH, CITY OF COVENTRY

No exhaustive search of epidemiological history is necessary to find arresting evidence of the relationship between travel and the spread of disease The propagation of plague along the trade routes of the world in the Middle Ages, the importation of syphilis to Europe from Hispaniola in 1493, and the world-wide transmission of influenza in 1918, are but three of innumerable examples The paths of infection from country to country coincide faithfully with the routes of human travel and the rate of spread is determined by the speed of human transport. The advent of air travel is therefore of obvious significance.

The potentialities in respect of generalized aerial navigation to day find universal acceptance. They bring sweeping social changes, no less in importance than the annihilation of distance and the lowering of geographical barriers Moreover they accord to each centre of population the possibilities of a port The public health problems associated with these developments are receiving careful consideration by the Office International d'Hygiène Publique, in consultation with the International Air Navigation Commission, and it is likely that a convention for the sanitary control of aircraft will be available ere long to contracting nations Meanwhile little has been contributed to the medical literature on a subject which is of intriguing interest and of undoubted moment

Novel Contingencies

The contingencies introduced by aerial navigation and relevant to our theme are chiefly as follows

1 Journeys from distant infected countries are accomplished within the incubation periods of the major infectious diseases

2 Illicit landing or forced landing of aircraft may result in importation of infection at places other than authorized air ports equipped to deal with it

3 Rapidity of travel may be responsible for the arrival of infected live mosquitos (say from yellow fever zones) in countries ordinarily unfrequented by them

4 Aircraft, while over land, may let fall refuse matter capable of conveying infection Peculiar difficulties also obtain in the matter of sanitary provision on board

Air Travel and the Major Infections

Incubation Periods and Rapidity of Transport

In the light of propagation by air travel, the main diseases to be considered are plague, cholera, yellow fever, small pox, and typhus For this purpose, the incubation periods are taken to be respectively six, five, six, fourteen, and twelve days The accompanying table illustrates the significance (as far as concerns this country) of these figures in connexion with the first contingency mentioned above

It is clear that in the case of apparently healthy passengers arriving in this country by air from local areas infected by one or more of the diseases named, surveillance will be necessary until expiration of the incubation period or periods This surveillance will presumably devolve on the health department of the area constituting the ultimate destination Detention on arrival, pending expiry of incubation time, is clearly unwarrantable, for such a course might well nullify the very expedition which prompted air as against sea transport There are certain instances where even surveillance can be dispensed with, as for example, persons (arriving within the incubation time from a local area infected with small-pox) who possess immunity from the disease as a result of (*a*) a previous attack of small-pox or (*b*) evidence of successful vaccination performed not more than (say) four years and not less than (say) twelve days previously. In the event of actual occurrence of infectious disease during the air voyage, sanitary precautions on arrival will be similar to those imposed in the case of shipping

Major Infection	Incubation Period	Infected Countries Trafficking with Great Britain	Time of Journey to England by Sea	Corresponding Time by Air
Plague	6 days	India	21 days	6 days
		Malaya	26 ,,	8

It is necessary of course that all air passengers should be free from manifest infection on embarkation and that aircraft, prior to departure from infected areas, should undergo cleansing, deratization (against plague contingencies), and disinsectization (against typhus and yellow fever)

Yellow Fever

According to British legislation affecting port sanitation, yellow fever is placed with plague and cholera in the category of important health hazards Although yellow fever assumes first importance, in connexion with inter travel between certain countries over seas, it is difficult, even with the advent of aerial navigation, to regard the importation and spread of the disease in this country as a serious danger The position however justifies full examination

Yellow fever infection cannot pass from man to man save through the intermediate agency of a specific type of mosquito, commonly regarded in the past as the *Stegomyia fasciata* or *Stegomyia calopus* but now named the *Aëdes aegypti* (the term adopted in America) or the *Aedes argenteus* (the term used by the British Museum) In order to enable spread of yellow fever in Britain, therefore, there must be a case or cases of the disease together with available mosquitos of the type above mentioned or the presence of *Aedes argenteus* containing the yellow fever virus ingested elsewhere In regard to the yellow fever hazard in this country, therefore, the relevant questions are (*a*) Can *Aedes argenteus* be imported here alive and continue to live thereafter in our climate? (*b*) Can the yellow fever virus exist in this country? The adventitious importation of the *Aedes* is readily conceivable—above all given rapid transportation by air It is further conceivable that infected mosquitos thus introduced, provided that hot weather prevailed here at the time, might live sufficiently long to infect persons with yellow fever It is clear, however, that the *Aedes* could not ordinarily exist here for any appreciable length of time and that therefore it could not give rise to any serious outbreak of yellow fever in our midst In this connexion, Professor J G Thomson of the London School of Hygiene and Tropical Medi-

* Read in opening a discussion in the Section of Public Health including Tuberculosis and Occupational Diseases) at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

cine, informs me that "*Aedes aegypti* (*Aedes argenteus*) cannot establish itself permanently and breed further north than latitude 40° (that is, about the south of Spain) This mosquito imported accidentally into England would perish with the onset of the first cold spell of weather" When the fact is added that the yellow fever virus itself cannot ordinarily tolerate our climate, it is evident that the epidemiological dangers in Britain in respect of yellow fever are not great Although local contingency is thus remote in this connexion, nevertheless it is not without precedent, as for example in 1865, when a ship (the *Hecla*) from Cuba arrived in Swansea with yellow fever aboard A considerable number of further cases of the disease then occurred after arrival among the crew and among men on shore who were engaged in unloading the ship, and several deaths ensued Doubtless this incident is explained by the unusual fact that the *Aedes* had arrived in large numbers on board ship and had propagated the infection during the short period of their subsequent existence Presumably the length of time of a sea voyage from infected areas ordinarily secures the death of mosquitos accidentally taken on board Rapid transport by air is not so likely to ensure this, and special precautions will need to be taken at air ports in yellow fever zones to make certain that departing aircraft are mosquito free

Other Major Infections

The dangers of propagation by air travel of plague, cholera, small pox, and typhus are so patent as not to warrant lengthy treatment here The health problems entailed are similar to those connected with sea transport, save for the special considerations already dealt with in previous sections of this paper The rat problem in plague and the vermin problem in typhus are clearly important Rat harbourage in aeroplanes is very limited, although instances are by no means unknown of rats being located in them The holds of airships present greater dangers in this connexion The occurrence of vermin on passengers by air or in their personal effects is very unlikely, for the cost of long distance air transport will, for many years to come, preclude participation by the transmigrant and immigrant classes

The Problem of Forced and Illicit Landings

Sea going vessels of necessity can enter only those ports equipped by nature or by engineering skill to receive them Aircraft are not thus limited by physical circumstances and may conceivably therefore land at unassigned places The danger of importation of infection in this way is not entirely theoretical The problem is common to Customs and sanitary authorities, and its recognition is evident from the fact that the law in this country prescribes authorized places of embarkation and disembarkation, and ordinarily requires their exclusive use In the case of forced landings of aircraft from foreign countries, doubtless it will be made incumbent on the pilot or "master" to notify the nearest Customs and sanitary air port Illicit landings will be suppressed by due application of the law, although this will be no easy matter if, and when, privately owned aircraft come into common use for international travel

Sanitary Problems on Board Aircraft

The voidance of refuse from aircraft presents a peculiar sanitary problem The sea constitutes a ready means of disposal in respect of waste and sewage from shipping Sewage matter from trains is voided in small amount on to the tracks, but the latter are used only by rail traffic The release of refuse from aircraft while crossing land may possibly produce outbreaks of infectious disease—for example, if excreta falls into water courses The danger is more than theoretical in the case of aircraft from a country such as India with the risk of typhoid or cholera infection on board It is clear that a stringent rule, of international application, will be necessary to prohibit the voidance of refuse from aircraft while over land

The ill fated R101 possessed eight sanitary conveniences fitted with water flushing systems The sewage matter was flushed into a retention tank below, the intention being to empty the tank only while passing over the sea It is clearly necessary aboard an airship to reduce weight to a prescribed minimum, thus it is difficult to carry an adequate supply of water solely for flushing purposes The possibility has been considered of collecting waste lavage water and utilizing it for closet flushing On the whole it would appear that even a limited water carriage system is impracticable on aircraft and that therefore a conservancy system of disposal is usually necessary on long distance machines

The sanitary accommodation on the R100 consists of pails in which earth or a disinfectant is used These can be voided while passing over the sea or at the end of a voyage The Graf Zeppelin is fitted with a type of valve closet Into the basin the user places a conical receptacle of stout paper, after use the valve is opened and paper cone and contents are dropped into a retention tank below It is evident that all these methods constitute a forced reversion to crude sanitation which is not free from health risks

The heating and ventilation of long distance passenger aeroplanes and of airships have peculiar difficulties Aeroplanes are usually heated from the engine exhaust, and a careful system of jacketing is necessary to prevent any possibility of escape into the aeroplane of injurious fumes In airships, heat can be derived either directly or indirectly from the hot water of the motor engine radiators Heating by electricity was tried in the R100, but it is likely that the former method will prove the more satisfactory The problems attendant upon ventilation of aircraft are occasioned by the various air currents and eddies encountered during flight These matters are receiving the attention of technical experts, and solutions are being evolved

Air Port Sanitary Services

In course of time many civil aerodromes will come to be established in various parts of the country and certain progressive municipalities have already taken steps in this direction For the most part, these aerodromes will be used only in connexion with intra national airways, a selected few will be recognized as Customs and sanitary airports for purposes of international aerial navigation To the latter medical and sanitary personnel will be attached for duties similar to those performed by the staffs of existing seaport sanitary organizations Although there is something to be said for an air port sanitary service controlled centrally, as the Customs waterguard, the duties entailed will devolve more naturally on the sanitary authorities of the areas in which the aerodromes are situated It is not difficult to envisage the time when sanitary air ports will compare in importance, from the public health viewpoint, with the seaports, but that time is not yet

Plans were shown outlining the systems of water supply and sanitary provision on board the airships R100 and the late R101 For access to these plans the writer is indebted to the Director of Airship Development, Royal Airship Works, Cardington

"PROMINENT HEEL"

BY

PAUL BERNARD ROTH, F.R.C.S.

ORTHOPAEDIC SURGEON, MILLER GENERAL HOSPITAL

A condition which appears to have escaped all mention in books is one in which pain is complained of over the back of the heel on the outer side.

A lady, aged 29, states that she has been slightly troubled with painful lumps on the back of her heels for years, and that lately they have got much worse and much larger, so that now it is almost impossible for her to wear any shoes without considerable pain.

On examination a localized swelling is observed on the outer side of the back of the os calcis, about half-way down, opposite the lowest limit of the insertion of the tendo Achillis. This is tender on pressure, is very hard, and gives the impression of being due to a bony outgrowth. One is strengthened in this belief by the fact that there does not appear to be much thickening of the skin, such as one finds in a callosity.

In a lateral *x*-ray photograph, however, no bony prominence is seen, and one is led to think that the lump must be due to a thickening of the fibrous tissue covering the back of the os calcis, perhaps, indeed, to a thickening of the periosteum. This is obviously due to irritation caused by the back of the shoe not fitting the heel properly, and the shoemaker receives the blame for this. Several cases which the writer has seen lately suggest that the shape of the os calcis may be the cause, and that the shoemaker is not alone at fault.

In *Cunningham's Anatomy* the posterior extremity of the os calcis is described as "of oval form and rounded surface," and several drawings are given which bear this out. On examining the three specimens in my possession I found that this description applied only to one of them; when the other two were placed in the position they occupy in the foot and looked at from above, they both projected markedly backwards on the outer side (Fig. 1), so that the description "oval or rounded" does not apply. I went then to the College of Surgeons Museum, and found that out of forty bones no fewer than fifteen projected backwards on the outer side in exactly the same manner. We therefore arrive at the fact that seventeen out of forty-three os calces examined, or 39 per cent., have this shape, and may conclude that it is common and of almost normal occurrence. From the nature of the projection it cannot be seen in the lateral radiogram, only from above or below. I believe that when we meet with the condition of painful lump on the back of the heel we are dealing with a case where this prominence exists to an extra degree. Shoes are made with symmetrical backs, and where this prominence is marked there is likely to be undue pressure and eventually a painful lump (Fig. 1). That it does not happen more often is remarkable, and must be attributed to the adaptability of the tissues.

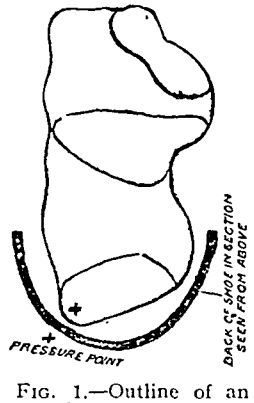

FIG. 1.—Outline of an os calcis (left) from above, showing projection backwards on outer side and its relationship to back of shoe.

DIAGNOSIS

If it be remembered that the painful lump is situated over the outer side of the back of the os calcis, about half-way down, there can be no difficulty. The more it feels and looks like a bony lump the more the diagnosis is confirmed.

Other conditions for which it might be mistaken are: (1) inflammation of the bursa beneath the tendo Achillis, or of the skin over the latter, both of which are in the middle line; and (2) apophysitis of the os calcis, a diffuse swelling involving the whole of the back of the heel and occurring only in adolescence.

TREATMENT

1. *Palliative.*—With the avoidance of all pressure for one or two months the lump will disappear. This necessitates the wearing of shoes with no backs, or with the backs cut out opposite the lump. I advise my patients to wear "mules," keeping them from slipping off, if necessary, with elastic bands. A moderately high heel is theoretically of advantage, as it reduces any strain there may be around the insertion of the tendo Achillis. Recently a mule with a loop to *encircle the tendon* has been put on the market, which is excellent; and Lilley and Skinner have produced a walking shoe on the same principle (Fig. 2). Resolution may be hastened by daily massage and by the application of a lanoline compress at night. Wearing boots instead of shoes, in the belief that it is the slipping of the shoe alone which causes the trouble, will not be effective. High heels are not the cause either; the worst case met with was in a girl, aged 15, who wore flat-heeled brogue shoes.

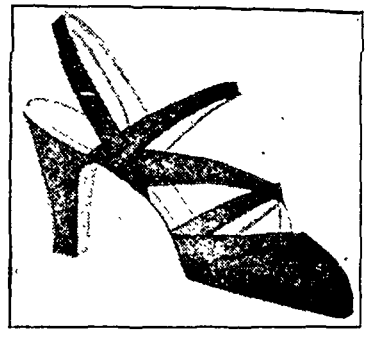

FIG. 2.—A walking shoe which does not press on the back of the os calcis.

2. *Preventive.*—If care is not taken the lump will return, for shoes are made on the assumption that the backs of people's heels are of "oval and rounded surface." After perfectly fitting shoes are obtained, preferably by being made to measure, the backs of them opposite the site of the lumps should be beaten out slightly by the shoemaker.

3. *Operative.*—Removal of the prominence by open operation is entirely uncalled for.

NOMENCLATURE

As there is already a condition known as "painful heel" (pain and tenderness in the centre of the heel underneath, involving the posterior attachment of the plantar fascia), it is suggested that the present trouble may be named "prominent heel."

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

ZOSTER, HICCUP, AND VARICELLA

Modern work on zoster and varicella has been extensive, and seems to have demonstrated on both clinical and experimental grounds the existence of a definite etiological relationship. Cases where rashes of zoster and varicella occur simultaneously in the same patient are not, however, very common. Bokay[1] recorded twenty-nine such cases, while Russell Brain[2] has recently commented on their concurrence. Paton,[3] these authors, and others have also adduced strong evidence in favour of a close relationship between encephalitis lethargica, zoster, and varicella. In

[1] Bokay, J.: *Jahrb. f. Kinderheilk.*, 1928, cxix, 127.
[2] Brain, W. Russell: *Lancet*, 1930, ii, 70; *British Medical Journal*, 1931, i, 81.
[3] Paton, L.: *Brit. Journ. Ophthal.*, 1926, June, 305.

view of this relationship, the incidence of a well-known symptom of encephalitis lethargica—hiccup—is of particular interest in a case in which zoster and varicella occurred simultaneously.

J. C., aged 70, was admitted to St. Mary's Hospital on January 17th, 1931, complaining of persistent hiccup and a rash on his left leg. He gave a history of indefinite malaise and anorexia beginning on December 24th, 1930, followed three days later by a severe attack of hiccup, which persisted for the next three weeks in spite of energetic treatment by his doctor, including administration of half-grain doses of morphine. On January 1st, a dull burning pain began in the left knee and radiated to the groin. Three days later a rash developed in that area, accompanied by an inguinal adenitis. From that day until January 17th, when he was admitted to St. Mary's, the rash and pain had increased, while the persistent hiccup had produced considerable distress.

He was, on admission to hospital, a heavily built, exhausted patient, who hiccuped approximately every four seconds. Scattered irregularly over his abdomen, chest, back, arms, and legs was a vesicular rash, in various stages of development and in every way typical of varicella, and which the patient had entirely failed to notice. In an area corresponding to the peripheral distribution of the left second and third lumbar roots was a most profuse zoster rash, and with it a similarly limited area of hyperaesthesia. The left knee-jerk was absent. Temperature, pulse, and respiration were normal, and remained so during his stay in hospital; no other abnormal signs or symptoms were detected.

Examination of the cerebro-spinal fluid showed: fluid clear and colourless; pressure normal; cells, 14 per c.mm., mainly lymphocytes; globulin increased; Lange curve 0012211000; glucose, 0.07 per cent.; chlorides, 730 mg. per 100 c.cm.; no bacteria seen; culture negative. Injections, intracerebrally, intrathecally, and intradermally, into a monkey and rabbit were kindly carried out by the Lister Institute, but gave negative results for an ultra-microscopic virus. The Wassermann reaction was negative. In view of the maturity of the zoster and varicella rashes, no attempt was made to look for an ultra-microscopic virus in the vesicles. White blood cells were 9,000 per c.mm., and the differential count was normal.

The patient was given 1 grain of nembutol, which checked the hiccup for eleven hours. The dose was then repeated and no further hiccuping occurred. The zoster and varicella eruptions faded, and after a fortnight had practically disappeared, leaving little scarring. The left knee-jerk returned, but remained diminished relative to the other side, while the hyperaesthesia became replaced in about a fortnight by a diminution of sensation to light touch and pinprick of patchy distribution in the area concerned. The burning sensation in this zoster area persisted, and on January 30th, a month after the onset of the disease, occurred the first of a series of typical and intense attacks of post-herpetic neuralgia. *X*-ray therapy was given by Dr. H. C. Gage, and consisted of a series of nine exposures of the skin area and lumbar roots involved. Dosage: at first, four-fifths B, later one-half B, Sabouraud pastille units, on each occasion with the intervention of a 3.5 mm. aluminium screen. Under this treatment the attacks of neuralgia diminished in frequency and intensity, and finally ceased on February 9th. The patient was discharged cured on February 28th, and has attended the out-patient department on two occasions since to report that he is still free from symptoms.

The case is important as illustrating the relationship between zoster, varicella, and encephalitis on the one hand, and hiccup and encephalitis on the other; for, while it is possible to account for the symptoms manifested by the assumption of a coincidence—that of simultaneous infections—it seems a simpler and more probable view that the whole chain of events was related by an infection due to one virus.

I am indebted to the Lister Institute for their interest and care in investigating the cerebro-spinal fluid, and particularly to Professor F. Langmead for his help and his permission to publish the case.

W. D. W. BROOKS, B.M., B.Ch.Oxon.

St. Mary's Hospital, W.2.

Reviews

A SYSTEM OF BACTERIOLOGY

Of the two remaining volumes of this *System*,[1] which is being produced by the Medical Research Council, volume viii has now been published. In the main it is devoted to the pathogenic fungi, fungi imperfecti, and the spirochaetes. Chapter I deals with the fungi, the major portion having been written by J. Ramsbottom, with a section on the ringworms by Arthur Whitfield. This account suffers from condensation, carried so far as to render it almost useless to the medical reader. The author, Dr. Ramsbottom, is not altogether to blame, for he preludes his section with the remark that "the space allotted to mycology is so restricted that it is impossible to cover the field even in summary." Yet he has attempted to do so, with the result that it is almost unintelligible to those without a good grounding in mycology. We should have thought that, in view of the limited space, it would have been better to attempt to delineate some of the pathological pictures which fungi can produce in man, mentioning the more common pathogenic species, rather than aim at an exhaustive survey. The section of this chapter on ringworms is valuable. The clinical appearances and the pathology of these conditions are clearly described; in fact, the whole story is presented in a more orderly manner than is usual with this subject. The next chapter contains an account of the actinomyces, and opens with a clear account of the aerobic forms, by R. St. J. Brooks.

The anaerobic actinomyces, of most importance to bacteriologists in this country, are described by L. Colebrook, and he has given us an excellent account, which concludes with a most useful summary of the principal lines along which further research is required. The chapter ends with a short note on actinobacillosis by F. Griffith. Following this is a useful chapter on the pathogenic leptothricae by Ivy Mackenzie, and then we pass on to the spirochaetes, which take up the major portion of the volume. Chapter IV, by E. Hindle, is concerned with a general survey of spirochaetes. The author adopts Dobell's classification, no doubt with good reason, and one gathers on page 105 that leptospira is discarded as a division of the pathogenic spirochaetes. Yet he continues to use the term, and on page 296 refers to the subgenus leptospira; this is rather confusing. Chapter VI, on the blood spirochaetes, is particularly good, and contains much of interest, such as the changes in immunological type which occur in relapse and Nicolle's views on the origin of the different human strains of relapsing fever.

Some hundred pages are allocated to syphilis, and coming from an authority like Colonel L. W. Harrison the chapter on this disease is naturally a good one. From an article such as this one can get a good idea of the life-history of the disease—a difficulty which the student not infrequently experiences—and the questions of cultivation, natural and acquired resistance, and serological reactions, are dealt with in a clear and well-balanced manner. There is a short note on *S. cuniculi* by E. Hindle. Chapter VIII contains a short account of rat-bite fever by A. Robertson, and in the next chapter E. Hindle discusses the leptospiroses. There is obviously still a great deal to be done before the interrelationship of the various pathogenic leptospirae is cleared up. Even in Weil's disease the leptospirae exhibit a variety of serological types, a point of importance in relation to the serological diagnosis of this condition, and one which the

[1] *A System of Bacteriology in Relation to Medicine.* Medical Research Council. Vol. viii. London: H.M. Stationery Office. 1931. (Pp. 390; illustrated. Single volumes, £1 1s. net; set of nine volumes, £8 8s. net.)

author omits to mention. Chapter XI contains a useful account, by J. and R. Cruickshank, on the normal flora of man. One could not hope for an exhaustive survey in so small a compass, but the absence of any mention of the filter-passing anaerobic bacteria commonly present in the upper respiratory passages is a surprising omission. This chapter is, however, fairly comprehensive, and should prove of considerable service to workers in that field of bacteriology. The two remaining chapters, on yaws and swine erysipelas, by Lieut.-Colonel A. Dawson and J. T. Edwards respectively, are both clear and concise.

" PROBLEM CHILDREN "

The Pattern of Life[2] is the name given to the record of a series of cases of problem children examined by Dr. Alfred Adler at the New School of Social Research in New York in 1929. The plan followed is similar to that which he demonstrated during his recent visit to London (*British Medical Journal*, January 24th, 1931, p. 139). The case notes are prepared by the medical man or teacher who has charge of the case according to a scheme originally worked out for the child guidance clinics which he established in Vienna. The notes are read out, and Dr. Adler comments on each paragraph before he sees the child at all. In most instances he is able to construct a picture of the child's personality, and displays extraordinary insight into the child's mind and sympathy with all the actors in that particular human drama. A brief discussion of the whole situation follows. Then one or both parents are brought in and questioned and instructed. Finally, the child is brought in, and the situation discussed with him in simple, kindly language. Not infrequently the child benefits almost at once from this simple instruction, which is always accompanied by frank encouragement. But Adler does not rely on " sudden conversion." The case is followed up by the teacher or physician who presented the history.

This book, then, aims at being a key to the art of reading case histories. Those who have seen Adler at work will realize his extraordinary skill in this department. The titles of some of the case notes will give an idea of the problems discussed: " The road to crime," " The boy who wants to lead," " The hunger strike," " The fear of growing up." The editor, Dr. W. Béran Wolfe, prefaces the case records with a short but lucid exposition of the Adlerian system of psychology. As he points out, the concept of the unity of the human personality, which is its foundation, is neither new nor unique. It underlies the Greek drama. Adler's second great principle is that the organism is a dynamic whole, moving through a definite life pattern towards a definite goal. Every human organism strives for a measure of security and totality which shall make continued existence tolerable. But the fate of the individual is inextricably linked with the fate of his group. This is a fundamental principle of Adler's individual psychology. The social life of the human race is an outgrowth of its weakness. Communal existence was probably the quickest and most effective way our ancestors could find of protecting themselves. All the strengths of the human race fit into a pattern, beginning in individual weakness and moving towards a goal of comparative security in social solidarity. All its weaknesses are derived from the danger of isolation. The human baby is the only animal that experiences his own inadequacy, because his mind develops faster than his body. Hence the feeling of inferiority. Far from being a handicap this feeling has proved itself the most powerful stimulus in the development of the human race. Each human being is capable of elaborating his personal defects into a useful contribution to society, yet comparatively few have the courage to effect such compensations. Our neurotics far outnumber our geniuses. The first factor, which intensifies the inferiority feeling until it crystallizes into an inferiority complex, is that of physical defect. This may be an actual organ inferiority, but it may be merely an unimportant physical anomaly, medically unimportant, but socially embarrassing, such as abnormal fatness, albinism, moles, or bow legs. The second group of factors which intensify the inferiority feeling deals with the social, religious, and economic condition of the individual. A third set of factors may arise from the child's position in the family; but it is one of the most important teachings of individual psychology—the first science to point out the significance of the ordinal position of the child in the family constellation—that no position can *compel* a child to become neurotic. The mother is the first person with whom the child makes social contact. Mother love is the first social approval. The mother has the double function—first, of reconciling the child to his situation in the world, and, secondly, of encouraging him to develop his own power of growth and adjustment to other individuals. This delicate role is naturally seldom played to perfection; there are several typical mistakes, all of which produce easily recognizable types of " problem "

[illegible]

feels and look

maintaining the " status praesens " and suppressing variations which are incompatible with it. The human will, it is true, appears to be a factor making for further development; but if we exclude artificial cross-breeding, which Darwin himself regarded as of trifling importance in comparison with the forces of nature, it seems to act rather in promoting the conveniences of life than in effecting organic changes—in adapting mankind more effectively to the present stationary circumstances, rather than effecting his further development. Whether an advance in intellectual capacity has occurred within the historical period is doubtful; advance seems mainly to have consisted in an increased power of utilizing the capacity we possess, thanks to the organized pursuit of knowledge. An interesting example of this is Sir Richard Burton's fruitful observation that the Somalis believed the deadly tropical fevers to be caused by the bite of the mosquito; brought under the purview of organized knowledge the relation between malaria and the mosquito was, as is well known, fraught with immense consequences.

Professor Almquist's book is largely concerned with a discussion of the present state of the organic world, but he has done an additional service in calling attention to the unjustifiable use which many authors have made of discoveries in this field of science, by building upon them, in dogmatic fashion, theories devoid of scientific foundation. To correct this misuse of scientific work he recommends that the writings themselves of the original discoverers should be carefully studied and the extent and limitations of their discoveries clearly defined. He has adopted this precept himself, and has furnished concise statements of what was really discovered by those included in his series of twenty-two short biographies, and what conclusions may legitimately be drawn from them.

LATERAL CURVATURE

The monograph by the late R. W. LOVETT of Boston, on *Lateral Curvature of the Spine and Round Shoulders*,[1] passed through several editions in his lifetime. We reviewed the fourth edition in our issue of February 9th, 1924 (p. 241). A fifth now appears, revised and edited by DRS. FRANK R. OBER and A. H. BREWSTER of Harvard University. They have brought it thoroughly up to date, and it may be considered to be the best treatise on the subject in the English, or perhaps in any, language. R. W. Lovett's judicial attitude of mind prevented his making claims of successful treatment which could not be substantiated. The hopelessness of improvement in some cases is strikingly portrayed at the end of the chapter on treatment, where, in five radiographs taken between 1903 and 1910, the history of a case is graphically shown, and the last state is worse than the first. Although we are not so informed, we should surmise that this was one of those particularly resistant cases caused by congenital defect of the body of a vertebra. In other cases represented the results of persistent treatment with corrective jackets are most encouraging. The editors are cautious in their remarks on incisive operations for scoliosis. The Hibbs operation, which is that most in vogue, seems to offer the best prospect of arrest of deformity. It was discussed in our annotation of March 28th, 1931 (p. 550).

In this edition there has been added a description of the method of treating scoliosis by Galleazi of Milan, and a detailed description of the turnbuckle plaster jacket treatment, which, when properly carried out, gives encouraging results. There are many new illustrations, and the sections on exercises are to a large extent also new.

CORPORAL FUNK

The Cross Bearers[2] is a translation from " Die Pflasterkästen," by A. M. FREY. It is a war novel about the German Army Medical Corps. The hero—for among other things he appears anxious to prove his claim to be considered as such—is a medical orderly called Funk—an unfortunate name from the translator's point of view. He served for three years on the Western Front at a regimental (brigade) dressing station. His main occupation seems to have been keeping records, labelling the sick and wounded, and libelling his superior officers. In the end most of his " scribbling " was so much wasted effort, because the records he compiled were all lost. In spite of this he was awarded the Iron Cross and the Bavarian Cross of Merit, and was promoted to the rank of corporal. *The Cross Bearers* ensures that his views on German medical administration will not share the same sad fate as his admission and discharge books. The intention of the book is pacifist, and if it succeeds in its mission so much the better, but it is too prejudiced in its outlook to encourage that hope. It may have lost in translation. Several parts are inclined to drag. A certain interest attaches to the description of the methods adopted by the Germans in disposing of their sick and wounded, and the increasing difficulty of evacuation due to the gradual failure of transport. At the same time those who were familiar with the different sectors of the British Front will find entertainment in reading of places behind the German lines with which they were formerly familiar, at least on the map. Corporal Funk appears to have been unfortunate in his experiences. The officers, both regimental and medical, whom he served under, and the other ranks with whom he was associated were lazy, indifferent, and idle. All were filled with an overruling ambition to get away from the Front as soon as possible. It may be correct that the German Army Medical Corps was not as highly organized as were those of some of the allies. We are not prepared to admit that it was as inefficient as A. M. Frey would have us believe. We would prefer to believe that the German doctors, working under endless difficulties, with paper substitute bandages, with unreliable hypodermic syringes, and with such things as antitetanic serum cut down to vanishing point, continued to do their duty to the end. Throughout the book are interpolated the usual sordid love affairs, from which it appears impossible to escape in a certain class of war book.

NOTES ON BOOKS

A good little book with a title which is not wholly appropriate is *Fathers and Sons*,[4] by Mr. E. B. CASTLE, the head master of Leighton Park School, Reading. Some exception may be taken to the title because, though the volume is described as dealing with " the important aspects of adolescent training that belong to the province of the parent rather than to that of the teacher," and though it does here and there make some attempt to justify and to imply this distinction, in fact it is concerned generally with those matters which come within the province of both parent and teacher, and which many may think can be dealt with even better by the teacher than by the parent. The author is himself fortunately both father and teacher, and can therefore appreciate the position of both with reference to each of the two subjects mainly discussed in his book. These subjects are the attitude and methods which should be adopted in reference to the instruction and guidance of boys on sex matters and on matters of religion. In regard to both, there are many wise words and practical suggestions in the book, and the two subjects are kept in proper proportion and

[4] *Fathers and Sons.* By E. B. Castle, M.A.Oxon. London: University of London Press, Ltd. 1931. (Pp. 160. 3s. 6d. net.)

duly related to one another. It is here emphasized, what is only too often forgotten, that in each case it is not only knowledge which has to be imparted, but conduct which has to be inculcated, and that the object is always to encourage a good life as well as an intelligent attitude. Some of the author's aphorisms may be quoted as examples of his quality: "There is a world of difference between a mother's love and a mother's apron strings." "Knowledge does not change appetite, though it may, indeed, be a handmaid to virtue." "The harm that was once done to the body by the exaggerated claims of religion is now done to the soul by an exaggerated respect for the body." Attention may be drawn, also, to the appositeness of the chapter headings, especially those taken from Wordsworth's *Prelude*, and so, through them, to the extreme beauty and psychological value of a great poem which is now not so often read through as it should be. Mr. Castle's book is the more timely and useful as a very relevant contribution to the debate started at the Annual Meeting of the British Medical Association at Eastbourne by Canon Pym, and reported in the *Journal* of August 1st last (pp. 186 and 215).

The tenth edition of *Black's Medical Dictionary*[7] has now appeared; the fact that this brings the total number of copies printed to 82,000 indicates the popularity that has been won. Dr. J. D. Comrie, who has edited this book since its first appearance in 1906, has taken advantage of the opportunity provided by the new edition to make a large number of minor alterations in order to bring it up to date as regards recent advances in treatment and changes in legislation affecting medical practice. The general purpose of the dictionary is to make available for nurses, teachers, health visitors, employers of labour, and other laymen such information and guidance with regard to medical matters as is likely to be of practical help to them in preventing disease, and in co-operating with medical practitioners in treatment. Simple drawings and diagrams are used to elucidate some of the descriptions, the print is clear, and the tabulation of the matter facilitates quick reference. The new edition will, without doubt, be as generally welcomed as its predecessors.

A short but detailed and attractive biography of Dr. Antonius Manasseh[8] has now been prepared by C. G. Naish, principal of the Brummana High School in the Lebanon, for the many friends in this country and in Syria of a medical pioneer who won high esteem as superintendent of the medical work of the Friends Foreign Mission Association, and in connexion with the Syrian and Palestine Relief Fund. He was once described in the *British Medical Journal* as "a bridge between individuals and peoples who misunderstood one another." Dr. Manasseh was largely concerned with the introduction of modern medicine into a country where the age of magic was still continuing. The biography indicates how he was able to achieve his great success; it will be welcomed by many who had no previous knowledge of a very humble and most energetic member of the British Medical Association, who was equally at home in the East and in the West.

The book entitled *Le Sang*[9] is a French translation of Professor L. J. Henderson's well-known work on the physico-chemical system of the blood, in which the author has expressed the interdependence of the circulation, respiration, and the various functions of the blood and other physiological mechanisms and reactions by nomographic diagrams and equations. It includes many tables setting out the details of analyses of blood under different conditions, arterial and venous, during rest and exercise, among normal people and in pathological states, showing the variation in amounts and in the distribution of gases, salts, and proteins in serum and cells. The subject is a difficult one, and of specialized interest, belonging to the physico-chemical district of physiological inquiry, and has at present but remote appeal to medicine or clinical practice. The translation reads easily and follows the arrangement of the English edition. From a cursory comparison the tables and diagrams seem to be carefully reproduced. The smaller size and diminished weight are definite advantages over the original volume.

We have received the first volume[10] of the Reports of the Hospital del Rey, Madrid, published under the editorship of the director, Dr. M. Tapia. In addition to the hospital statistics and a list of the publications of the hospital staff from its foundation in 1925 to October, 1930, the volume contains eighteen papers, ten of which deal with various aspects of pulmonary tuberculosis, and the rest with summer typhus, typhoid fever, stomatology, poliomyelitis, and pneumonia.

PREPARATIONS AND APPLIANCES

A Sterilizer Control

The Drayton Regulator and Instrument Company Ltd., of West Drayton, Middlesex, which specializes in the production of automatic regulators for the control of heat, humidity, and pressure, has brought out a simple and inexpensive device for preventing damage to electrically heated sterilizers due to boiling dry. The boiling dry of the sterilizer is a trouble not at all infrequent, and may occasion very serious inconvenience and expense. Various preventive devices have been tried, generally based on the thermostatic principle, relying for their operation on the rise in temperature of the bottom plate of the sterilizer when this becomes uncovered. These devices, however, have not always proved satisfactory; they give the

warning when the damage has perhaps already begun. In this new device the thermostatic principle has been entirely discarded in favour of a simple form of float-operated switch. It consists of a small circular copper float, with a lever, and a mercury make-and-break, which may be of 3, 6, or more amperes, operated by the float. A direct safeguard is afforded by the position of the float, so that the matter can be rectified before trouble actually arises.

We are informed that the device has been extensively tested by sterilizer manufacturers, who are agreed that it is satisfactory in its working and positive in its indications. The simple construction, which involves no great modification in sterilizer design, is apparent from the drawings of the float switch, in straight or in angle pattern, which we reproduce.

Sodium Morrhuate for Injection

Sodium Morrhuate B.D.H. is a preparation of this drug recommended for the treatment of varicose veins. The makers (British Drug Houses Ltd.) supply the drug in a 5 per cent. solution with 0.5 per cent. phenol added as a preservative. They also supply a 10 per cent. solution for veins that prove exceptionally refractory to treatment.

HUNGER PAINS IN PYLORIC AND DUODENAL ULCER

It is now thirty years since the symptom-complex which was previously considered characteristic of gastrosuccorrhoea—namely, periodic occurrence of epigastric pain and vomiting some time after a meal, together with hypersecretion of gastric juice, and often with retention of gastric contents—was described by Moynihan as indicative of duodenal ulcer. This group of symptoms was later established by Faber as characteristic of the juxtapyloric ulcers on both sides of the pylorus, differentiating them from ulcers of the body of the stomach. The "pyloric syndrome," as it is called, though most frequent in the presence of a juxtapyloric ulcer, may sometimes appear in cases in which resection of the stomach does not reveal an ulcer but a pyloric gastritis. Later authors claim that the symptom-complex may be a sign of pyloric gastritis, and the frequent occurrence of this group of symptoms in patients with verified juxtapyloric ulcer may be due to the coexistence of ulcer and pyloric gastritis. Among the various features of the symptom-complex chief importance has been attached to the late pains, or, in milder cases, the late discomfort—that is, the periodic pains or discomfort in the epigastrium do not set in immediately after the meal, but occur so long after it that the stomach may be assumed to be empty or nearly empty. These late pains (the "hunger pains" of Moynihan) are further characterized by being relieved by the ingestion of suitable food.

Up to the present two theories as to the cause of the hunger pains in juxtapyloric ulcer have held sway. According to one theory, the pain is primarily a result of increased acidity of the stomach contents, at the height of or at the end of gastric digestion. The acid may in general have an irritating effect on the pain-producing mechanism; or the hyperacidity is supposed to irritate the mucous lining of the stomach, which again, by reflex action, gives rise to spasm and in this way to pain. According to the other theory, the pains are chiefly due to abnormal motility (spasms or increased peristalsis), and it is probable—though still uncertain—that the abnormal motility is produced through hyperacidity of the stomach content, which thus indirectly takes part in producing the pain. In a recent series of experiments Dr. Oline Christensen[1] has investigated patients presenting the symptoms of hunger pains, with a view to determining whether the so-called hunger pains are principally connected with the motility or the secretion. The balloon method of Boldyreff was adopted. The patient swallowed a sausage-shaped balloon, about 6 inches long and 2 inches in diameter when inflated, attached to a rubber tube connected with a manometer, and continuous records were made of the movements of the stomach. By means of a signal the patient could indicate simultaneously on the record the occurrence of pain or discomfort. A preliminary series of observations on normal individuals demonstrated that the empty or nearly empty stomach has alternating periods of vigorous contractions and almost absolute rest, but no relation was found between hunger sensation and contractions of the empty stomach such as was described by Cannon and Washburn, and by Carlson. When the stomach contains food, however, the contraction curve is changed, and the alternation of strong contractions and absolute rest gives way to a condition of weaker contractions of constant slow rhythm. Meals rich in protein and fat give longest relative rest before the onset of vigorous contractions takes place.

In patients with duodenal ulcer—a series of eighteen unselected patients in Professor Knud Faber's clinic—Dr. Christensen has shown a distinct connexion between the hunger pains and the hunger contraction periods of the stomach. The pains were never present without the gastrographic curve showing a concurrent contraction period, and no registration of an attack of pain was made during a period of absolute rest in the stomach movements. The hunger pains would always begin sooner or later after a contraction period had started, and would cease when this period was replaced by absolute rest or a few minutes after. Once the pain had appeared, some of the patients would register continuous pain throughout the contraction period, whereas others would register intermittent pain. When the pains are relieved by intake of food, it is owing to the vigorous contractions being replaced by periods of gentle slow contractions or relative rest. As a result of these investigations it may be said that if a patient is examined during an attack of typical hunger pains, the gastrographic curve will show vigorous stomach contractions. The reverse, however, does not hold good, so that the hunger pains cannot be regarded as depending entirely upon motor conditions. On the other hand, there was no relation whatever between the spontaneous or induced variations in the acidity of the stomach contents and the appearance or the intensity of the pain. The apparent relief of the hunger pains by taking sodium bicarbonate is more likely to be due to the filling effect on the stomach of the carbon dioxide produced. Dr. Christensen found that patients treated for gastric ulcer often showed a higher acidity in a test meal after a cure and when all symptoms had disappeared than when treatment was started. This was also observed by Hurst and Venables in their cases of duodenal and gastric ulcer.

Since, therefore, there seems no connexion between the appearance and intensity of hunger pains and the variations in the acidity of the stomach contents, it is possible that, as several investigators have demonstrated, the hunger pains are a symptom of pyloric gastritis. It is reasonable to assume that the greater or lesser

[1] *Pathophysiology of Hunger Pains: Gastrographic and Titrimetric Investigations.* By Oline Christensen. *Acta Medica Scandinavica, Supplementum* xxxvi. Copenhagen: Arnold Busck. 1931. (Pp. 170; illustrated.)

degrees of tenderness in the inflamed wall, due to circulatory disturbances, may be related to variations in the occurrence of the pains, and that the seasonal occurrence of the pains may be associated with exacerbation and improvement of the gastritis.

INDUSTRIAL HEALTH

The eleventh annual report of the Industrial Health Research Board[1] summarizes the work of the Board for the last five years. It differs in character from previous summaries, for the earlier work of the Board related largely to the fatigue of the worker in heavy industries, and the means of mitigating it by reduction in the hours of work and the introduction of rest pauses. The present report, though it discusses at some length the heavy work of coal miners, especially in relation to absenteeism, deals more particularly with light industrial occupations involving repetition work. Such occupations do not induce much physical fatigue, but are a potent source of monotony and boredom to some of the workers, though many of them—particularly the women—prefer this type of work, as it allows unlimited day-dreaming and requires no concentrated mental effort. Persons temperamentally unsuited to monotonous work are generally of a higher type of intelligence than those who prefer it, and their uncongenial tasks offer no scope for them to exert their powers. It is therefore very desirable that they should be sorted out from their fellows by suitable vocational tests, and as far as possible assigned to work for which they are better suited. Some of the Board's investigators are engaged in devising vocational tests, but it is not easy to find reliable tests which can be applied easily and with certainty. A not inconsiderable proportion of the workers are of the nervous and emotionally unstable type, and are specially apt to be temperamental misfits in their employment. Tests have been devised for identifying these workers, but they have not yet reached a very practical form, though good progress has been made. Again, methods of reducing monotony are being studied, for all types of worker engaged on repetition tasks are bound to suffer from monotony to a greater or less extent. It is found that monotony can be considerably reduced, and output at the same time improved, by allowing the operatives to change their work periodically, by supplying them with material in small quantities at a time instead of in bulk, and by allowing them to work in compact social groups rather than as isolated units.

Owing to the change in the character of its duties the title of the Board was changed, about two years ago, from "Industrial Fatigue Research" to "Industrial Health Research," and a number of statistical investigations have been made with the specific object of studying the sickness rates of large groups of workers in certain industries. For instance, it has been shown that the artificial humidification of weaving sheds, against which an outcry is periodically raised, is not associated with any increase of sickness among the weavers. The investigation related to the sickness of 20,000 operatives, half of whom worked in dry sheds and half in sheds humidified by the introduction of steam or atomized water, so that the results of the comparison can be accepted with confidence. A second investigation related to the sickness of card-room workers, and it was found that workers of 30 and upwards showed three times as much sickness from respiratory causes as their fellow workers in other parts of the mill. Again, an investigation of sickness among printers showed that they suffered a considerably higher death rate from tuberculosis than other occupied males, though their death rate from other causes was lower than the average. Health depends to a large extent on the bodily adaptation of the worker to his task, and a statistical survey of the physique of women afforded information concerning the optimum weights which should be handled and carried. The liability of industrial workers to accidents is well known, and it is found that certain individuals are much more "accident-prone" than the average. Tests are therefore being devised for identifying such workers, with the ultimate aim of transferring them to occupations in which they have but little scope for exhibiting their unfortunate propensity. Accident frequency is also influenced in no small degree by the conditions of work, such as lighting, temperature, and ventilation, and the better these conditions the lower the accident rate.

The physical conditions of work are of very great importance to all classes of industrial workers, whether employed on heavy work or on light work, and a large part of the Board's activities relates to the elucidation of the best conditions of work, and the effects of departures from these conditions. Though a great deal of investigation has been made in the past upon the influence of atmospheric conditions, much remains to be done. Novel methods of heating buildings—such as panel-heating, under-floor heating, and high-temperature overhead radiator heating—are being introduced, and the application of these methods to industry needs close investigation. The favourable influence of good lighting has been quantitatively investigated in compositors and others, while the benefit of magnifying spectacles to normal-sighted persons has been demonstrated in a number of occupations involving fine work. For instance, the "linkers" of hosiery, the women mounting small electric lamp filaments, and those examining steel balls for defects, have to bring the eyes to within ten inches of the work, and this involves considerable eye strain. The use of spectacles with lenses of 1.5 to 4 dioptres and with prisms improved output by about 10 per cent. and greatly relieved the strain. A physical condition of environment which has received much attention in the public press of recent years is noise, and several of the Board's investigators have made preliminary attempts to gather information on the subject. It is very desirable to

[1] Medical Research Council Eleventh Annual Report of the Industrial Health Research Board Including an analysis of work published during the years 1926–30. London: H.M. Stationery Office 1931 (1s 6d. net)

obtain a reliable objective test for noise, but hitherto success has not been achieved. So far as can be ascertained, industrial workers—with few exceptions—do not object to the noise incidental to their occupation, but clerical workers are more sensitive.

BRIGHT'S DISEASE

A valuable account of a series of cases of Bright's disease has recently been published in *Medicine*, and reprinted as a separate Medicine Monograph.[1] It represents the labours of a team, headed by Drs. Stillman and van Slyke, who have worked for several years in the hospital of the Rockefeller Institute, New York. The chief merit of this monograph is the extreme care with which sixty-seven cases of differing types of nephritis have been investigated for years, and often followed to necropsy. The exactness of the observations reflects the ample facilities provided for such work in this special hospital for the investigation of disease. Questions of nomenclature are always a matter of interest in writings on Bright's disease, and in this monograph the terms used are a mixture of those of Volhard and Fahr (1914) and of Addis (1925). The differences between the two terminologies are, however, clearly explained. The term "degenerative Bright's disease," used by Addis, is preferred to "nephrosis." One of the most striking points to a British reader of this monograph is the emphasis placed on the term "haemorrhagic nephritis," which includes the whole group of cases in which the glomeruli are affected. Fifty-one out of the total sixty-seven cases are placed in this group—twenty-three being acute, two latent, thirteen active chronic, and thirteen terminal. Haematuria is the sign which distinguishes this group from all others (including the so-called nephrosis), and indicates that the glomeruli are involved in the disease. Gross haematuria in the early acute stage of Bright's disease is a commonplace finding, but in this monograph the authors, following Addis, lay great stress on the haematuria to be detected even in the most latent stages of the disease. A special method for the recognition of scanty haematuria, recommended by Addis, was used only in the later stages of the investigation. It consists in giving the patient a dry diet for twenty-four hours, and in centrifugalizing the concentrated urine obtained in the second twelve hours. The authors state that the degree of initial haematuria in glomerulo-nephritis has no bearing whatever on prognosis, and that in two cases only of their series did haematuria disappear during the latent stages of the disease. They point out, and with this we agree, that latent cases in which haematuria disappears for a time may, in the absence of a good history of the initial acute stage, be mistaken for pure cases of degenerative Bright's disease or nephrosis. It is these cases, we think, which constitute the rare examples of nephrosis which progress to renal insufficiency and end in uraemia, while at necropsy healed or partly healed old glomerular lesions are found. Another problem given much prominence is that of renal oedema. The authors support Epstein's views, and maintain strongly that loss of plasma protein is the main factor in renal oedema. They state that whenever the total protein content of the plasma (average 7 per cent.) falls below 5.8 per cent., or the albumin fraction (average 4.3 per cent.) falls below 2.3 to 2.7 per cent., then as a rule oedema results. The globulin fraction, as is now well known, undergoes little change. The authors are forced to admit that there are other factors which influence the onset of oedema—toxins in acute nephritis, salt intake and output, cardiac failure, and so on; but with these minor reservations they are whole-heartedly of the view that "the constant and dominating factor in producing non-cardiac oedema in Bright's disease is plasma-albumin deficit." No reference is made to opponents of this view; for example, Elwyn's book *Oedema and its Treatment* (1929) is neither mentioned in the text nor in the bibliography. It would be pleasant to think that the problem of renal oedema is more or less solved on the plasma-albumin deficit hypothesis, but in the opinion of many the matter is far from being so simple and far from being settled. A full and excellent discussion of urea retention is given, and the authors have made much use of the test of blood-urea clearance elaborated by van Slyke and his colleagues in 1930. This test has so far not been given a sufficient trial in this country, but it must be done. It is well worth reading this monograph with care; its clearness and brevity of style are admirable. The charts are too small and condensed for the average reader, but if they are neglected this does not in any way spoil the reading of the text. As in all monographs on Bright's disease there is ample room for disagreement with the authors on a number of points, but that is merely stimulating. The bibliography given at the end mentions only papers quoted or referred to in the text, and thus a number of names associated with important and fundamental old and recent work on renal disease are altogether omitted. To have included them, and to have referred even briefly to their work and their views in the text, would, in our opinion, have added much to the value of this monograph and given it a better balance.

SHORTAGE OF R.A.M.C. OFFICERS

In the *Times* of August 7th there appeared a long and carefully reasoned letter calling public attention to the serious situation now existing in the Army owing to shortage of officers in the R.A.M.C. The signatories were Sir Alfred Keogh, late D.G.M.S., Sir Charles Burtchaell, late D.G. British Armies in France, Sir David Bruce, F.R.S., Sir T. J. Gallwey, and a number of other distinguished men who have held high positions in the Army Medical Services. After analysing the situation, and indicating its dangers in peace and in war, they remind their readers that there have been many instances in the past of a shortage of officers arising from similar causes. "The cause," they say, "is mainly the same as it always has been when newly qualified medical men are not attracted to the Service—that is to say, the pay and pensions offered by the State have fallen behind the times in actual value, and compare unfavourably with other public appointments and with the emoluments and amenities of life incidental to the private practice available to-day to young recently qualified medical men of the ability and type that are suitable to maintain the efficiency of the R.A.M.C. Such young men, whose medical education has cost

them five or six years of time, and an expenditure of £1,500 to £2,000, will only consider entering the R.A.M.C. provided the initial rate of pay is at least as good as that for other public appointments open to them, and if the larger emoluments of civil practice are compensated for by the certainty of a pension absolutely and relatively commensurate with what they renounce by embarking on an Army career." The only remedy, in their considered opinion, is an immediate increase in the pay and pension, and improvements in the status of all officer ranks of the Corps. "We urge that these three essential points must be dealt with in an adequate way on the lines specified in the report of the committee of the British Medical Association which investigated the conditions of service of the R.A.M.C. early this year." It is greatly to be hoped that this manifesto, written in plain language and influentially signed, will carry conviction in the quarter that matters most at this stage—namely, the committee of inquiry appointed by the Prime Minister to report on the dearth of medical officers in the three Services.

THE CAMPAIGN AGAINST VENEREAL DISEASE

The Union Internationale Contre le Peril Venerien, on which serve the representatives of forty-four countries, members of either Government venereal disease departments or of voluntary organizations recognized by Governments and devoted to the campaign against venereal disease, has, for the past year, been reviewing the general position with regard to treatment. As is well known the action taken officially in different countries varies considerably—from the complete scheme adopted in this country to more limited schemes, dealing with the treatment of syphilis only, in certain others. There has been much controversy on the Continent as to the extent to which State funds should be expended in the treatment of disease, some taking the view that the immediate disinfection of the patient was all that the State should be required to undertake, while others, such as the representatives of Great Britain and of the Scandinavian countries, urged that full and complete treatment of the patient, until cure, was the responsibility of the State in the interests of preventive medicine. After several conferences and very full discussion a resolution was unanimously adopted, to which we are asked to draw the attention of medical practitioners in this country. It runs as follows:

"The Union, having taken note of the reports presented by Professors Bayet, Jeanselme, and Jadassohn on the general principles of the antivenereal campaign, from the point of view of society as much as of the individual, invites all Governments, public authorities, and antivenereal associations to ask the medical profession to take its stand, in the duty which every doctor, specialist or

[illegible] owes to syphilitic patients, on the following four the trial rules: First, and above all, if the patient is con- ago, from [illegible] his period of contagiousness to a dustrial Health Researc[illegible]diate and intensive treatment. vent the reappearance of con- investigations have been [illegible]iently active and prolonged of studying the sickness rates [illegible] prevent all possibility of in certain industries. For instais to the offspring. The [illegible]pecially that the fight carried on (*a*) by a in the family as (*b*) by treat- congenital syphilitics, but by sufficiently regular and prolonged treatment of the parents before procreation, and of the mother during pregnancy. Fourthly, as far as at all possible, to protect the patient against the future personal consequences of his syphilis in such a manner as to secure the definite disappearance of the treponemae from the infected organism."

SUPPRESSION OF ASBESTOS DUST

Since knowledge of the ill effects of asbestos dust in inducing fibrosis of the lungs was made prominent, notably by Dr. W. E. Cooke in his discovery of the "curious bodies," the Home Office has set speedily to work, not only to gain more knowledge as to its prevalence, as in Dr. E. R. Merewether's report[1] (noted by us in our issue of April 26th, 1930, p. 789), but also now in the report before us on methods for suppressing dust in asbestos textile factories.[2] This last document is particularly interesting in that it deals with agreements come to by a committee consisting of engineering inspectors of factories and representatives of the trade. It is a pleasing instance of the readiness nowadays of leading manufacturers to combine with the Factory Department to do everything practically possible to suppress dust, and to pool for the benefit of their industry their experiences in regard to the problems to be solved. No comparatively harmless form of asbestos is known, so that no substitute is possible, as in the Sheffield grinding industry through the replacement of sandstone by artificial stones made of carborundum. Amelioration of the conditions is therefore to be sought in what is after all the sheet anchor for the protection of workers in dangerous trades—locally applied ventilation by fans so contrived as to operate on the dust as nearly as may be at its point of origin and to prevent it entering any room where persons work. On this matter fresh ground is broken, although it might be thought that little that is new could be said. With material which starts in the form of lumps of mineral ore and emerges as a spun, woven, fibrous material, every opportunity for the evolution of dust is given in the successive stages (to mention only the principal) of crushing, disintegrating, pulverizing, teasing, sieving, mixing, blending, screening, and carding. Big hopper hoods enveloping dusty heaps and machines have been commonly used in the past, but they are here discarded, and their place is taken by infinitely more effective closely fitting covers, to the sides of which the exhaust ducts are connected, where the draught will be at its maximum. How ingeniously this can be effected is well illustrated by numerous diagrams of the processes and ten photographic plates. The expense in fan power and galvanized iron piping must be enormous. These agreements are to be embodied in statutory Regulations to govern the industry. A note of hesitancy appears here and there in the report as to whether later exhaust may not have to be applied to such processes as spinning, winding, and doubling—so subtly may the dust lay down the new fibrous tissue in the lung like a spider's web. These spinning and doubling processes were those from which Dr. Merewether laid down his "dust datum,"

[1] Effects of Asbestos Dust on the Lungs and Dust Suppression in the Asbestos Industry. By E. R. A. Merewether, M.D., and C. W. Price. London: H. M. Stationery Office. 1930. (1s. 3d. net.)

[2] Report on Conference between Employers and Inspectors concerning Methods for Suppressing Dust in Asbestos Textile Factories. London: H. M. Stationery Office. 1931. (1s. net.)

below which application of exhaust ventilation might be regarded as unnecessary. In a further paper by him, however,[1] a list is given of fifty-one determinations of the dust content of the atmosphere of workrooms and other places from which this dust datum was obtained. The discrepancy shown between the figures for spinning and those for carding and other dusty processes is not very striking, and not one of the determinations dealt with winding and doubling. The ensuing Regulations will mark a great advance, and perhaps bring about almost total disappearance of the disease.

POST-VACCINAL ENCEPHALITIS

The difficulties surrounding the problem of the etiology of post-vaccinal encephalitis are made manifest by the lack of success which has attended all attempts to find its solution. Opinions on this problem are sharply divided. One school maintains that the condition is due to an unknown neurotropic virus which is lit into activity by the invading vaccinia virus—postulating a similar etiology for those cases of encephalo-myelitis complicating occasionally the exanthemata—while the other holds that vaccinia virus is alone responsible. In view of this impasse any possible new light on the problem is worthy of consideration, and should not be disregarded without a careful scrutiny. Dr. J. R. F. Rassers of the University of Leyden in a monograph entitled *Encephalitis Post Vaccinationem*,[2] puts forward his views on this problem and brings forward experimental evidence purporting to support his thesis, which is briefly as follows. He accepts the view that the infection of the central nervous system is the work of the vaccinia virus alone, but to account for the prevalence of post-vaccinal encephalitis in the last few years and its relative, if not complete, absence in earlier times, one must postulate an increased virulence of the virus. This increased virulence might of course be absolute or relative, and Rassers inclines to the opinion that the change is in the susceptibility of the individual to the vaccinia virus, and he considers this to be due to an excessive use of salt in our diets. On the Continent there is a school of dermatologists which attributes many skin conditions, such as skin tubercle and exfoliative dermatitis, for instance, to eating too much salt, and it claims to cure or considerably improve these dermatoses by merely putting the patient on a salt-free diet. Rassers shares these views, and in his monograph he brings forward evidence to show that dogs placed on a salt-free diet are practically insusceptible to vaccinia virus, whereas those with a high salt intake react intensely. But that is not all. Eight out of ten dogs on a salt diet developed encephalomyelitis after an interval of ten to twelve days after vaccination in the majority of cases. It is true that it was not proved that the encephalo-myelitis was due to the vaccinia virus, nor was this condition histologically similar to post-vaccinal encephalitis in man. Further, it would seem highly improbable that excessive salt-eating bears any relation to the incidence of post-vaccinal encephalitis. Nevertheless, should Rassers's facts be substantiated he will at least have drawn attention to an interesting phenomenon.

"NOBLESSE OBLIGE"

It was a new line of thought that was pursued by the Chairman of the Charities Committee in presenting its report to the Representative Body of the British Medical Association last month. The needs of the recipients, the appeal *ad misericordiam*, have hitherto been stressed, and these needs are ever more and more importunate. But there is another stimulus which may be applied to our generosity. The history of "these charities" when put together forms a sum of brave endeavour; it tells of fine and wide ideas arising in the hearts and minds of quite humble and ordinary members of the profession, in large measure carried out in spite of apathy and discouragement, maturing into a body of benevolent effort which deserves more hearty and widespread support than has up till now been accorded to it. If we reflect upon what must have been the position in the early years of the Benevolent Fund of the Association, when after four years of struggle it found the claims upon it such that it was deeply in debt, and yet it determined to "carry on," we marvel at the faith and vision of these devoted men. Yet from such feeble beginnings these early members of the Association held on and worked on for a third of a century; by which time they had made good and were fit to stand alone as a separate off-shoot from the parent organization under the name of the Royal Medical Benevolent Fund. Its "opposite number" in Ireland was the product of the vision of a solitary Irish country doctor, William Kingsley, who devoted his life to the creation of this society. Epsom College was even more daring in its conception. John Propert, a Welsh club doctor in London, had vision. His thought was for the establishment of a home, not only for the sons of doctors, but a foundation something like that of the Charterhouse, where in the evening of their days men might rest who had been worn out in the service of medicine. It was a noble conception and, although never fully realized, deserves our admiration. Another consideration is also forced upon us. We know that the actual maintenance of these charities is being carried on principally by personal contributions from medical men and women, thus keeping us in line with the great non-medical charities such as the Freemason's. A natural result of the position which all such charities have attained is that the care of their own people falls upon them, and the medical charities are now in like case. From this we must conclude that by us and by no others can the work be done. That it is a necessary work and one that should appeal to all members of the medical profession is evident to anyone who reads the records of the cases that are presented for help. Hastings and Kingsley and Propert were wise in their prevision; they are men of whom our profession is proud; and we may feel that it lies with us as a point of honour to maintain and extend the work which they began: *Noblesse Oblige*.

On July 18th the honorary degree of Doctor of Medicine was conferred on Dr. Harvey Cushing by the Budapest Royal Hungarian Peter Pázmány University.

We regret to announce that Lieut.-Colonel J. R. Lord, C.B.E., M.D., medical superintendent of the Horton Mental Hospital, Epsom, died on August 9th. We hope to publish an obituary notice next week.

SECTION OF MEDICINE

Friday, July 24th

EXOPHTHALMIC GOITRE

Professor F. R. FRASER, in opening the discussion, said that there had been three main lines of advance in recent years. The first was the connexion between the morbid anatomy and the clinical condition. The histological picture was very varied, and in understanding it the previous history of the gland must be taken into account. Stimulation of the gland produced hyperplasia and hypertrophy; when stimulation ceased involution occurred, but this did not necessarily mean the return of the picture to normal—there might be hyper- or hypo-involution. He then discussed the bearing of these studies on the varied appearance presented by patients showing symptoms of thyroid intoxication. These could be largely explained by variations in the intensity of the stimulus, the varying response of the gland, and the capacity of the organs of the body to withstand the intoxication. The second was the therapeutic use of iodine. As yet there was no explanation of the action of iodine. It caused the disease to run at a lower level, and was of great value in the preoperative treatment of cases to be submitted to surgery; in this connexion, he persisted with it for much longer periods than the ten days so dogmatically advised in the literature. The third was the development of surgical treatment. Professor Fraser showed tables to demonstrate the results of medical and surgical treatment. In consideration of these it appeared clear that behind the exciting causal factor there must be some constitutional factor. As soon as diagnosis was made treatment must at once be instituted to diminish the amount of functioning thyroid tissue. Iodine should be given, and possibly some form of radiation; if improvement did not occur surgery must be employed, provided that skilled surgical assistance was available. As the result of his experience with hospital cases he was more and more impressed with the advantages obtained by surgical treatment.

Dr. J. EASON (Edinburgh), in discussing the etiology, said that in his series of cases emotional disturbance was a factor in 62 per cent. of them; frequently this had its origin in sexual matters, and reticence often made its appreciation difficult. In 23 per cent. there was an infective factor, but it was clear that some form of diathesis must be supposed. As in hysteria, there were different thresholds for different individuals. In his opinion the essence of the predisposition lay in an interdependent instability of the emotional, autonomic, and endocrine responses. Many cases were treated surgically because, for various reasons, adequate attention had not been given in the early days. At the onset the treatment was medical. He demonstrated the advantages of potassium iodide over Lugol's solution, and then passed to the results of radium therapy. This needed only one day every two months, so that patients could continue at work. In forty cases so treated seven were cured and seventeen showed marked improvement and were working with comfort. Of 133 cases of non-surgical treatment in ten years only nine were known to be dead, and only eighteen had not replied. In considering Professor Fraser's figures, he felt that he himself must be dealing with a much milder disease.

Dr. E. P. POULTON spoke of treatment by deep *x* rays. He described the improvement obtained, and quoted figures demonstrating successful results in about the same percentage as in Professor Fraser's operated cases, and about twice as good as several series of medically treated cases. He was therefore forced to ask "Why operate?" He drew attention to the extreme muscular weakness that was one of the features of the disease, and the effect of iodine in decreasing the pulse rate, illustrating these points by personal experience.

Dr. W. L. WATT gave further details of the cases shown in Dr. Poulton's table, with illustrative cases. He pointed out the advantage of combining deep *x*-ray therapy with surgical treatment, and said that relapses occurred in about 20 per cent. of cases treated surgically. By giving full sarcoma doses the time necessary for cure was greatly diminished. Mr. JOHN MORLEY (Manchester) pleaded for a carefully thought-out plan from the outset by the doctor in charge. Mild cases could often be cured by *x*-ray treatment, but this must be rapid in its effect; if after three months' trial the result was really promising it might be continued; if not, the aid of surgery should be called in. In toxic adenoma he thought *x* rays had little or no success. Operative risk could be greatly minimized by careful preparation—for example, by the administration of iodine and digitalis, by adequate rest before operation, and by a diet rich in carbohydrates. He preferred local anaesthesia as a general rule. Mr. W. H. C. ROMANIS described various types of disease, and declined to include cases which merely showed the presence of a soft goitre associated with palpitation or nervousness. He thought there must be, in addition, some abnormality of eyes or heart. Except in very early cases he looked on medical treatment as merely preparatory to surgery. He had seen little benefit from *x*-ray or radium therapy. The chief surgical mistake was to remove too little of the gland.

Mr. T. P. DUNHILL said that in the majority of cases, if at all severe, the damage that was already done was, to some degree, irreparable. Medical treatment did produce considerable improvement in most early cases, and some severe ones, but no case must be left too long, and all must be watched carefully, with the closest co-operation of physician and surgeon. Too frequently, although the symptoms were relieved in great part, full capacity for work was not regained because of the damage inflicted in the earlier stages. The indications for *x*-ray treatment were becoming more clearly recognized; it was unsuitable in very severe early cases and in cases in which complications had arisen. He described the favourable results obtained by operation in cases showing auricular fibrillation and glycosuria. It was wiser to leave children till development was complete, but it was not always possible.

Colonel MCCARRISON referred to the effect of nutrition on the thyroid gland, and spoke of his animal experiments, which showed that hyperplasia might be produced by dietetic conditions. By giving a diet with insufficient vitamin A, physiological deficiency could be induced, with the production of a condition of lymphadenomatous goitre. He suggested that the future might show exophthalmic goitre to be not primarily a disease of the thyroid gland. Dr. SUMMERHAYES, speaking from the point of view of the general practitioner, expressed the difficulty in getting patients to go up for operation in the early stages. He regarded the cases excluded by Mr. Romanis as being the early form of the disease, which required treatment. Professor RABINOWITZ (Brooklyn, N.Y.) reminded the meeting of the intimate connexion between the thyroid and adrenal glands, and suggested that in the future denervation of the adrenals might replace thyroidectomy. In the diagnosis of the disease he stressed the information to be given by an examination of the skin, which in these cases was always warm and moist. He also spoke of the supraclavicular nodules, which sometimes gave

origin to a faulty diagnosis of carcinoma. Dr. FLORENCE STONEY (Bournemouth) pointed out the need for discovering the exciting factor, and in this connexion emphasized the importance of not overlooking the presence of sepsis and of fibroids in the uterus.

SECTION OF SURGERY

Friday, July 24th

SURGICAL TREATMENT OF TRIGEMINAL NEURALGIA

At the meeting of the Section of Surgery, with Mr. H. UPCOTT in the chair, Mr. GEOFFREY JEFFERSON opened the discussion on trigeminal neuralgia. He said that the cause of trigeminal neuralgia was unknown, and that adequate treatment depended on the selection of the right cases. Neuralgia was a very uncommon disease, but was much commoner in the female; the pain was always confined to one side, and generally to one division at the outset, but might spread to the other divisions later. The neuralgia might appear on the opposite side years after treatment of one side. It was pointed out that the apparent differences in neuralgic pains were the result of the varying methods of description used by different patients; but, nevertheless, the pain was always essentially different from the pain of an inflammatory lesion. Tic douloureux was not a good term to use, since facial spasm was not a feature of all cases, and was rarely of a severely spastic or clonic type. Painful facial spasms might occur in cases not suffering from trigeminal neuralgia. Long remissions of symptoms were a characteristic feature of the complaint, and these periods of freedom from pain made the patient—and often his doctor—postpone any radical treatment. The distribution of the neuralgia was usually strictly anatomical, and, in the speaker's cases, commenced most often in the second division. Probably the second and third divisions were affected equally. It was not true that the pain usually affected the third division and then spread upwards to the second. Early affection of the first division occurred only very rarely, pain in the forehead was due to an overflow, or could be explained on anatomical grounds as originating in the second division or third division. The recognition that the ophthalmic division could be often spared profoundly modified the treatment of neuralgia. Neuralgia of the second division tended to be seated in the soft parts of the face. Third division pain was deeply seated in the bone and gum, and it was notable that pain in the tongue and lip was not as a rule marked.

Mr. Jefferson described in detail the features of the atypical neuralgias, and emphasized that the pain never remitted, and was never so suddenly severe as in the true paroxysmal neuralgias. The patients were usually younger, and both sides might be affected. Surgical treatment of this type was useless and should be avoided, since it usually made the condition worse. There was one case of glosso-pharyngeal neuralgia in the speaker's series. The pain was localized to the depths of the ear and fauces. It was more localized and deeply seated than in trigeminal neuralgia, and was brought on, not by movement of the jaws, but by swallowing.

In true paroxysmal trigeminal neuralgia there was never any alteration in the sensory perception of the skin other than hyperaesthesia. Pain due to tumours or focal leptomeningitides affecting the root of the nerve, tumours or aneurysms affecting the ganglion, or growths infiltrating the divisions was associated with anaesthesia and analgesia of the affected area. In rare instances, acoustic neuromata had been found in cases thought to be plain neuralgia, but he thought that this was not sufficient reason to adopt the routine approach to the sensory divisions through the posterior fossa.

Referring to treatment, the speaker said that removal of the lower two-thirds of the ganglion with preservation of the ophthalmic division, as perfected by Hutchinson, gave an extremely low mortality of 4 per cent. This was due to the fact that the danger of injury to the cavernous sinus was much lessened by partial removal of the ganglion. There was, however, usually a small opening made in the sinus when the cut second division was stripped back. Mr. Jefferson favoured Spiller's and Frazier's method of fractional division of the sensory root. In this operation there was no likelihood of damage to the cavernous sinus. In his own series of 86 cases, he had had two deaths, both of which were not due to technical error; he wished to point out that the risks of operation on the sensory root were extremely small. Division of the sensory root was a difficult operation, but, when performed correctly, the operative risks were negligible. The advantage of fractional route division was that the fibres in the route which supplied the eye were preserved, and, as in Hutchinson's partial ganglionectomy, the sensation of the eye was retained, and neuro-paralytic keratitis prevented. Frazier had shown that the arrangement of fibres in the route was such that partial division could be carried out with success. The anatomical arrangement was well shown by excellent illustrations. In the experience of the speaker, the safest way of preserving the motor route was to cut through the sensory route from without, inwards, until a hole was made through which the motor root could be seen. Cases in which alcohol injections had been made presented more difficulty, since there were adhesions, and separation of the fibres from one another did not occur so readily; also the motor route was often adherent to the sensory part. Mr. Jefferson said that he divided the lower and outer two-thirds of the root, the resulting anaesthesia affecting the lower two-thirds of the face and half the cornea. The partial retention of sensation in the cornea was sufficient to prevent neuro-keratitis. He had succeeded in dividing the middle portion of the sensory route in patients whose pain was chiefly referred to the second division. Anaesthesia following partial division was never dense, and since it stopped the neuralgic pains with partial preservation of sensation, it was a great boon to the patient. The motor route should always be conserved if possible, and Marshall's investigation of Mr. Jefferson's cases showed that there was no lessening in anaesthesia when the motor route was preserved. Peripheral alcohol injections had proved their usefulness, and the speaker considered that in the less severe cases limited to one division an injection of alcohol should precede the operation. This gave the patient a foretaste of the numbness permanently produced after root section. If fractional root division was to be performed, this was not so necessary, as some sensation was retained. He believed that injections into the ganglion itself should only be used in patients unsuited for operation. He arbitrarily fixed the age limit for operation at 70 years. In younger patients fractional root section was the best method of treatment: this operation enabled the surgeon to preserve at will such fibres as it was necessary to keep. Excellent diagrams were shown to illustrate the various points in his paper.

Mr. A. A. MCCONNELL (Dublin) said one should hesitate to make a diagnosis if the patient was young, or if the pain was in the region of the eye. He mentioned lesions of the eye and ear he had seen after repeated injections aimed at the second and third divisions at their exit from the skull. Too prolonged injections postponed operation till the patient was less able to stand it. He had seen only one post-operative death, which was due to neglect to place a plug of muscle in the opening leading to the posterior fossa, with the result that through it leakage of blood took place and set up symptoms of basal meningitis. He believed that there was no major

operation which old patients stood so well as section of the posterior root. The average age in his cases was 65, the oldest patient being 84.

Mr. H. S. Souttar said that division of the sensory root was a good method of treatment, but that too little had been said about alcohol injection. In his hands permanent relief of pain could be obtained. He said that success in this method of treatment depended upon the adherence to small details of technique. Mr. Souttar used Härtel's method with a slight modification. The foramen lay in a straight line, passing from a point one inch lateral to the angle of the mouth to the lambda. If the needle was directed at first towards a point slightly in front of the lambda it would finally strike the external pterygoid plate; the needle should now be slightly withdrawn, and then directed towards the finger situated at the lambda. If this technique was followed carefully very little difficulty would be experienced. A small amount of local anaesthetic should then be injected, and the position of the point of the needle confirmed by the resulting anaesthesia. On no account should an injection be given if cerebro-spinal fluid came from the needle. The speaker said that he injected 1 c.cm. of alcohol, and aimed at infiltrating the whole of the ganglion. The eye was stitched for five days to avoid keratitis. He regarded alcohol injection as the primary method of treatment.

Mr. Norman Dott (Edinburgh) said that the disease was a well-defined clinical entity, but that its pathology was obscure. As a rule there was no difficulty in diagnosis if the site, character, mode of precipitation, periodicity, and absence of anaesthesia, or evidence of involvement of other cranial nerves were carefully considered. Borderline cases, in his experience, were rare. The diagnosis could be confirmed by experimental nerve-block—preferably with percaine. Mr. Dott agreed with the previous speakers that the operative risks were very small, even in old patients. Fractional root section was the operation of choice when the first division of the nerve was not affected. If keratitis developed when all the sensory portion had to be sacrificed, he said that the eye should not be irrigated but protected from injury. Since there was no regeneration of the nerve proximal to the ganglion, cure was permanent. The speaker had given up alcohol injections, since he felt compelled to do so by the experience of his patients who had had injections before they came to operation. The fact that the operation was a permanent cure was an enormous relief to a patient who had been subjected to numerous alcohol injections. He himself had performed the operation sixty-five times, with no deaths, his oldest patient being 83 years of age. A case of bilateral trigeminal neuralgia successfully treated by operation was mentioned, and photographs of the present condition were shown. Preservation of the motor root was desirable in unilateral cases, and was essential in bilateral cases.

Mr. Donald Armour said that he would like to point out that division of the sensory root was performed by Sir Victor Horsley eight years before Spiller (who was credited with the operation) carried out the procedure. He did not agree that the diagnosis was so definite as Mr. Dott had mentioned. Trauma of the ganglion was possibly the cause of ulceration of the cornea, since he had successfully cured such an ulcer produced by previous alcohol injection, by removal of the ganglion. He mentioned a case of apparently typical glosso-pharyngeal neuralgia which was cured by injection of the Gasserian ganglion. If a patient refused operation it was improbable that he was suffering from neuralgia—this was a point in differential diagnosis. In conclusion, the speaker said that Horsley cut the motor root since he believed it contained some sensory fibres. Some of the recurrences after fractional root section might be explained if this fact were true. Mr. Upcott said that he had had a case with corneal ulcer after injection which was cured by removal of the ganglion. Patients who had been treated by operation were extremely grateful, but some had curious paraesthesiae in the anaesthetic area. The speaker had noted that there was loss of pain without total loss of anaesthesia after operation. In bilateral neuralgia operation was better and safer than alcohol injection. Mr. Jefferson, in reply, said that troublesome paraesthesiae as described by Mr. Upcott did occur, but were very uncommon. He did not believe that the motor root contained sensory fibres, and did not think that trauma of the ganglion had anything to do with keratitis. By the Härtel method the alcohol was placed in the roots of the nerve and not in the ganglion. Alcohol injection made subsequent operation much more difficult, owing to adhesions.

Burns and Scalds

The discussion on this subject was opened by Mr. Eric Lloyd with the paper which appeared in the *Journal* of August 1st (p. 177). In his introductory remarks Mr. Lloyd pointed out that the Registrar-General's figures in cases of deaths due to burns were to be relied upon, since all cases were subject to a coroner's inquest. These figures showed that though the mortality rate was diminishing, 1,700 deaths occurred yearly from this cause. Fraser's figures from Edinburgh in 1926 showed that the mortality rate in children under 10 years old was 38.7 per cent. He described in detail the general treatment of burns, emphasizing the importance of rest, warmth, fluids, and morphine. In local treatment, the use of tannic acid was a definite advance. It prevented the absorption of protein from the damaged area by coagulation; pain was strikingly lessened, and scarring was generally slight. The details of the technique of the tannic acid treatment were described. Temperature charts were shown illustrating the effect of blood transfusion and of tannic acid treatment, and compared with charts obtained before the use of such methods. Tannic acid as a rule prevented the toxaemic stage, and blood transfusion was now rarely necessary. Mr. Lloyd demonstrated pictures of deformities and disfigurements after burns, and described plastic methods for their cure.

Mr. J. Shirley Callcutt agreed with Mr. Lloyd about the liberal use of morphine in the early stages of burns—namely, in primary shock. He outlined the physiological state in secondary shock and its successful treatment, in desperate cases, with pituitrin. Referring to the question of sepsis he affirmed that it was very common, and should not be treated with moist dressings. He wished to draw attention to the prevalence of the onset of true scarlet fever within a few days of burns. Finally, he quoted a case of scalding with some dilute sulphuric acid agent, in which the scalds were extensive and primary shock profound, and which developed no signs of secondary shock. Mr. Dickson Wright said that there was often a good deal of pain and general upset when the scabs came off, leaving a septic field. He recommended spraying these painful septic areas with a solution of aspirin in water. He did not agree that pedicle grafts were desirable for burns, since the operations were moderately severe. He was of the opinion that Braun's method, tunnel grafts, or a method used by himself were much more satisfactory. Large, clean, granulating surfaces would often heal if they were strapped and left undisturbed for three weeks. He thought that the tannic acid treatment was an excellent method.

Mr. Eric Lloyd, in reply, said that scarlet fever was a fairly common occurrence after burns and also after operations on the mouth in children. He thought Mr. Dickson Wright's suggestions worthy of trial.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Friday, July 24th

ENDOMETRIOMA

The final session of the Section was occupied by the reading of several short papers. Dr. DANIEL DOUGAL (Manchester) opened the proceedings with a communication upon endometriosis and endometriomata. He defined endometriosis as the pathological state brought about when endometrial fragments invaded the uterine wall or, passing through the Fallopian tubes in regurgitant menstrual blood, reached the pelvic cavity and the structures within it. Cullen's diverticular and Sampson's retrograde menstruation, and cellular spill theories, were therefore accepted as providing the most reasonable explanation of uterine and extra-uterine endometriosis respectively. Endometrioma was defined as one of the tumours which developed when misplaced endometrial fragments or implants proliferated sufficiently to form clinico-pathological entities, and was accepted as the most suitable term to apply to all such tumours, whether uterine or extra-uterine. Dr. Dougal described the clinico-pathological features of the endometrium, and laid special stress upon the multiple character of the lesions resulting from endometriosis. The physical signs depended upon the situation of the tumour—in uncomplicated uterine cases there was usually a moderate and uniform enlargement of the uterus, but with cornual tumours there might be definite irregularity. In either case the physical signs closely resembled those of a uterine fibroid, and differential diagnosis was impossible unless increasingly severe dysmenorrhoea led to a suspicion of the true state of affairs. In ovarian endometrioma there was enlargement and fixation of one or both ovaries. There were no pathognomonic symptoms of endometrioma, but increasing dysmenorrhoea, menorrhagia, and dyspareunia should lead one to suspect the condition. The physical signs were more characteristic, and fixation of the uterus and ovaries associated with a shotty nodular tumour behind the cervix afforded almost conclusive evidence. As regards treatment, a conservative policy was only justifiable if one ovary was involved, or if there were isolated nodules in the recto-vaginal space causing dyspareunia. In 83 per cent. of his cases the uterus and all ovarian tissues were removed, the operation in the remainder consisting of excision of one ovary or of nodules in the recto-vaginal space. Owing to dense adhesions the operations were as a rule extremely difficult, but the results, both immediate and remote, were extraordinarily good. He preferred total to subtotal hysterectomy; it was unnecessary to excise infiltrating growths in the rectum or other parts of the alimentary tract, as atrophy would follow if both ovaries were removed. He had had no experience of radium in the treatment of endometrioma, because he preferred local excision in early cases as less likely to interfere with ovarian function.

The President, Mr. EARDLEY L. HOLLAND, said that he had never heard the subject presented so comprehensively and clearly as Dr. Dougal had done. Dr. MANWARING-WHITE (Hartford) said that he had had experience of one case. He could bear out what Dr. Dougal had said about symptoms. His case displayed extreme dysmenorrhoea, dyspareunia, and pain on micturition. Pain was so extreme that the patient was a complete invalid. In this case the tumour was in the recto-vaginal space. Pain persisted after operation until cured by deep *x*-ray therapy. He wondered whether these cases could not be treated from the beginning by *x*-ray therapy. Dr. DONALDSON said that he had had one case which did extremely well with radium treatment. The PRESIDENT remarked that he had seen a case involving the recto-vaginal septum. It was treated by a full dose of intra-uterine radium, and the result was almost miraculous. He raised the point as regards conservatism in operation: Was it advisable to remove the whole ovary or only to excise the affected part? His experience of conservatism had not been very satisfactory. As soon as destruction of the ovary was obtained symptoms abated. Mr. COOK asked how involvement of the umbilicus came about, and said that he would like to know what happened to endometriomata after the menopause.

Dr. DOUGAL, in reply, said he had no experience of deep *x*-ray therapy in these cases. He felt that the tragedy was that treatment, surgical or by radium, had to be so radical. He felt that some means of preserving ovarian function should be aimed at. He did not think there was any advantage in leaving part of an ovary behind. He thought it was not unreasonable that an implant might rise up on the fundus of the bladder, and so involve the umbilicus. He had operated on one case after the menopause, and there was some calcification of an endometrial cyst of the ovary. Ordinarily, symptoms should disappear after the menopause.

THE SHAPE OF THE PELVIC BRIM AND CHILDBIRTH

Dr. KATHLEEN VAUGHAN read a paper on the shape of the pelvic brim as a determining factor in childbirth. Workers in India and China knew that field workers had their children without difficulty: the town dwellers experienced great difficulty. The negress in natural surroundings had her children with ease; in America, when living in cities, they seemed to have increasing obstetrical difficulty. The reason must be disparity between the size of the foetal head and the brim of the pelvis. The female pelvis was subject to extreme variations in shape. She showed a series of tracings to illustrate this, taken from specimens of different races in the College of Surgeons museum—the shape of the brim determined the capacity of the pelvis. It would appear that the more primitive the conditions of life the more circular in shape was the brim of the pelvis; this was not so much racial in origin as due to conditions of life. Any variation in shape from the circular led to difficulty in the passage of the foetal head. Pelvic development depended upon the sacro-iliac joints, and ankylosis of one joint would cause failure of development of that side of the pelvis. In the open-air races the sacro-iliac joints were well and fully developed. Immobility of the joint led to changes in the shape of the pelvis. The whole pelvis was expanded to its greatest capacity in the squatting position. Exercise of the sacro-iliac joints led to freedom from obstetric difficulties. Dr. JANET M. GRAY confirmed the great difference between those who lived in the open air and those who lived in confined spaces. In purdah women difficulty was practically always met with. Dr. DOUGAL called attention to the strength of the uterine contractions, which were naturally stronger in open-air workers. This was probably due to a good supply of pressor substances being present in the uterus. A sluggish uterus was due to a deficient supply of these substances; secondary inertia might be due to the supply being used up.

HAEMORRHAGE AND SHOCK

Dr. O'DONEL BROWNE (Dublin) read a paper on shock following blood extravasations, with special reference to the treatment of accidental haemorrhage. Shock was produced by reabsorption of blood extravasated, and blood pressure fell markedly. Rapid pulse and sweating made their appearance when the pressure fell to 100 mm. Hg, and the symptoms became more marked the lower the pressure fell. The routine pre-operative treatment was warmth and elevation of the bed, submammary or intravenous salines, morphine, pituitrin, and ephedrine.

By these means a restoration of blood pressure was often obtained. In the more severe cases there might be no improvement until the extravasated blood was removed and prevention of its reabsorption established. A pint of saline under each breast was sufficient at a time, and might be repeated in an hour or two. In accidental haemorrhage rupture of the membranes was of importance. Plugging of the vagina undoubtedly aggravated shock, and did not affect the primary cause of the loss. In practice Caesarean section on a flabby uterus was definitely not harmful. He emphasized that the first step in the production of shock was a fall in blood pressure, and in face of a persistent fall of pressure means must be sought to locate and remove the extravasated blood. If the pressure fell below 80 mm. Hg in accidental haemorrhage, classical Caesarean section should be performed. Dr. DONALDSON referred to the theory of shock put forward by Bayliss. He asked whether in any of the cases referred to the specific gravity of the blood had been taken, and whether any animal experiments had been carried out to establish the presence of histamines. He deprecated the use of adrenaline in shock; he quarrelled less with pituitary, but did not value highly any drugs. Dr. ETHEL TOWNEND (Hull) asked whether tension, either intra-uterine or abdominal, had any influence in shock.

Dr. BROWNE replied that he was not in a position to say whether histamine was liberated or not. He had not estimated the specific gravity of blood in these cases. Adrenaline had not been used. Drugs coupled with extra fluid were beneficial. Gum saline he had not given, as it was not their routine at the Rotunda, but he thought it had distinct advantages.

SECTION OF DISEASES OF CHILDREN

Friday, July 24th

BIRTH INJURIES

Professor G. B. FLEMING (Glasgow), in opening a discussion on the recognition and treatment of birth injuries in the newly born, pointed out that the infant in its passage through the genital canal probably experienced severer trauma than at any future stage of its existence, and in contrast with the reaction to sepsis in the early days of life infants showed wonderful powers of resistance to injury. Dealing first with injuries to the skin and subcutaneous tissue he said that even in normal labours some damage to the skin nearly always occurred. More serious injury might be caused by forceps, while pressure sometimes caused the condition of adipo-necrosis neonatorum, with dusky-red indurated areas of swelling, disappearing in five to six weeks. Injuries to muscles included the well-recognized deformity sometimes produced in the sterno-mastoid muscle, which the speaker was inclined to think was due to venous obstruction and ischaemic contracture. The most common bone injury was fracture of the skull, and Professor Fleming urged that surgical intervention should as a rule be avoided. Fractured clavicle sometimes occurred, and was easily treated by placing a pad between the shoulder-blades and strapping the affected arm to the side. Fracture of the humerus was best treated by wrapping a thin layer of gamgee round the arm and encircling the limb from shoulder to elbow in a fairly firmly applied band of adhesive plaster. Injuries of the viscera, fortunately rare, were not often diagnosed during life, while of all the birth injuries those to the nervous system were most likely to leave serious and lasting disability. Facial paralysis was usually caused by pressure on the seventh nerve in its course outside the skull, mostly due to the application of forceps, and always passing off in one to two weeks. Injuries to the brachial plexus caused two well-known types of paralysis, probably due to overstetching of the nerve trunks. Early recognition of brachial plexus paralysis was most important, and the principle of treatment was to place the affected muscles in a position of relaxation and keep them there for at least six months unless recovery took place before that period. Injury to the spinal cord was commonly produced during breech extraction, and was treated by educating the muscles and sphincters. Intracranial haemorrhage was extremely common and very difficult to diagnose. A definitely pigmented or uniformly blood-stained spinal fluid with crenated red cells was probably the most important sign, but did not afford absolute proof. The essentials of treatment were skilled and careful nursing, with lumbar puncture as long as there were signs of increased intracranial pressure. In conclusion Professor Fleming pointed out that the prevention of birth injuries lay with the obstetrician and their treatment with the paediatrician. He emphasized particularly the prevention of sepsis in even the slightest superficial abrasion.

Dr. N. CAPON (Liverpool), carrying on the discussion, expressed his satisfaction that the paediatrician had now begun to have a better chance of observing the newly born, and drew attention to the enormous mortality among these children, which amounted to over 20,000 annually, even if the deaths labelled prematurity, atelectasis, etc., were excluded. He thought that instead of intracranial haemorrhage it was better to speak of intracranial trauma, since the physiology of the intra-natal period as it affected the child was imperfectly understood, and since the petechial haemorrhages occurring in the brain in many infants might be on the borderline between physiological and pathological. He preferred to divide all cases of birth trauma to the central nervous system into those with obvious haemorrhage and those without. Even the latter group might contain fatal cases, and the diagnosis in life was very difficult. Dr. Capon relied for differentiation on various points—the type of labour, the degree of maturity, the colour of the baby, the state of the sucking reflex, the type of respiration, and the general appearance of the child. Birth injury to the nervous system, he said, had to be distinguished from inanition fever, pneumonia, maternal poisoning, and, rarely, from some congenital abnormality of the brain. With regard to treatment he agreed that skilled nursing came first after prevention, but he expressed himself as finding great difficulty in knowing when to do a lumbar puncture.

Dr. AGNES BENNETT (New Zealand) commented upon the frequency of septic conditions in the newborn child, and said that she thought the term trauma or injury might be an awkward one for doctors to employ. Since so many of the cases of birth injury had some degree of haemorrhage she had lately been giving subcutaneous injections of blood in all such cases. Dr. DONALD PATERSON spoke of the great difficulty of making a differential diagnosis in practice when called to see a baby with some trouble immediately after birth. Intracranial trauma had to be diagnosed from the bleeding of the newly born, from curious "heart attacks," and from sudden "blue attacks." Some cases seemed to get better when fluid was given. Dr. HELEN MACKAY said that she also had great difficulty in separating out all the conditions occurring in the newly born. She enumerated the points which helped under the headings of the character of the labour, the colour of the child at birth, the pulse rate, the occurrence of twitching, difficulty in sucking, and of the type of cry. She had recently started giving blood injections to all babies with any suspicion of head injury. Dr. C. F. HARRIS spoke of the treatment of a group of such cases where breathing was the most trouble some feature, and in which he had found much help in the administration of carbon dioxide with oxygen.

CONGENITAL PYLORIC STENOSIS

Mr MAX PAGE in opening the discussion on this subject, said that the fact that he was introducing it indicated how surgical treatment of congenital pyloric stenosis had been accepted in this country, but the pre and post-operative care was still a matter for skilled medical care He outlined the principal points in the diagnosis of the condition, and advised operation as soon as the diagnosis was established As an anaesthetic he preferred ether given with an open mask, he went on to discuss various details of operative technique In some sixty cases thus dealt with at the Victoria Hospital he had had a mortality of 6 6 per cent, and in ninety cases at St Thomas's Hospital this was 12 2 per cent

Dr N MORRIS (Glasgow) spoke of the biochemical changes occurring in babies with pyloric stenosis There was an increased carbon dioxide content of the blood, brought about apparently by the loss of the chlorine radicle, and the type of depressed respiration which resulted might be sufficient to lead to diagnosis when it was recognized The gain in weight as the case improved was associated with a fall in the carbon dioxide in the blood Careful studies, however, showed that the chloride metabolism was upset altogether apart from the loss by vomiting, and it was possible that the primary cause of pyloric stenosis was a disordered metabolism of the alimentary tract in the neighbourhood of the pylorus leading to the elaboration of some histamine like substance, which, on absorption, caused abnormal metabolism of both chlorine and nitrogen From a practical point of view his studies led him to advocate cautious administration of saline to these cases, and on no account to wash out the stomach with an alkaline lotion

Dr DONALD PATERSON presented mortality statistics from the Hospital for Sick Children, Great Ormond Street, and showed that the mortality for the past few years had remained stationary round about 25 per cent In private practice, on the other hand, deaths after the operative treatment of pyloric stenosis did not occur, he attributed this difference entirely to nursing, and especially to individual care The type of operation or the surgeon did not appear to be important factors He discussed the danger of alkalosis in these cases, and described in detail the post operative feeding methods Dr JEVS SMITH made some remarks on a series of cases of pyloric stenosis and on babies who vomited without having this condition, in the light of clinical, radiographic, and biochemical findings She thought that the chemical changes found gave great assistance in both diagnosis and prognosis

Dr DOYNE BELL said that his contribution to the discussion was in a sense complementary to that of Mr Max Page, in that his observations were based on a series of 110 cases of pyloric stenosis from the children's ward of St Thomas's Hospital, the majority of which had been operated on by Mr Page The pre operative treatment of these children consisted essentially of gastric lavage with normal saline, and the subcutaneous infusion of 5 per cent glucose in normal saline After operation the child was fed hourly on a solution of lactose in water (one drachm of lactose to four ounces of water) for the first seven hours after which gradually increasing quantities of breast milk diluted with boiled water were given The progress to whole breast milk, seventy two hours after operation, was much slower than that outlined by Dr Donald Paterson but to this was attributed the avoidance of post operative gastro intestinal complications There had been no death from gastro enteritis in this series since the year 1923 The preponderance of first born children among infants suffering from this condition had been mentioned by Mr Page Dr Doyne Bell stated that in the series he was considering 50 per cent of cases had occurred in first born, 23 per cent in second born, 14 per cent in third children, 5 per cent in fourth children, and so on He had, however, compared these figures with those given in the 1921 Census for families with 1, 2 3 4, or 5 children, and had found that they corresponded almost exactly He considered, therefore, that the preponderance of first born children was of no significance whatever With regard to post operative pyrexia, the mortality among infants running a temperature of over 102° F, which formed 38 per cent of this series, was no higher than among those who showed no such rise of temperature after operation The value of x ray examination in these cases was small, 13 4 per cent of cases subsequently proved to have hypertrophic stenosis gave negative results with the barium meal Mr R A RAMSAY spoke of the importance of close co operation between surgeons and physicians in the treatment of this condition He had used local anaesthesia with great success in a large series of cases, and he thought that recurrent vomiting was always due to insufficient dividing of the hypertrophied muscle The post operative fever he attributed to the sudden access of food to the intestine

Dr HELEN MACKAY said that she preferred to give relatively concentrated feeds and to give the extra fluid as saline after operation on pyloric cases In the case of breast fed infants it was important to see that, where the milk supply was abundant, the baby did not get overfed too soon after operation Professor G B FLEMING said that the difficulty of treating children in hospitals was more a question of infection than of inefficient nursing which was usually better in institutions than in private

FACTORS DETERMINING EPIDEMIC DIFFERENCES

Professor MAJOR GREENWOOD opened the discussion with the paper printed in full in the *Journal* of August 8th

Professor W W C TOPLEY said that he could not answer the question before him, but could say something about the factors determining the difference between epidemic behaviour of one disease and that of another It would differ from that of another if the quality of the immunity differed significantly He would hazard a guess that solid immunity was a laboratory myth, although they could approach it more closely in the virus disease ectromelia than they could in the bacterial diseases Antitoxic immunity behaved in a similar way to antivirus immunity they were both highly effective over a wide range of conditions of exposure to risk, while the efficiency of anti bacterial immunity was of a far more relative and limited kind The possible significance of a variety of factors such as the influence of diet, of actual hunger and starvation, of fatigue, of climatic or seasonal factors, or of variations in the virulence or epidemic potency of the infecting parasite, could not be discussed at length, because, although it was probable that they exerted an influence, the definite proof that they did so was lacking

Lieut Colonel C A GILL said that the openers suggested that little advance had been made in their knowledge of this subject but he thought that they themselves had done a great deal to put this knowledge on a sound basis His own interest had been largely concerned with plague relapsing fever malaria and other protozoal diseases It appeared to him that there was a unitary mechanism of epidemiology in all diseases irrespective of the nature of the *materies morbi* Dr J D ROLLESTON observed that second attacks of diphtheria and scarlet

fever were recorded in the literature. He had had experience of one patient with a second attack of small-pox. Her first attack was confluent, and resulted in scars; she then went to work as a nurse in a small-pox hospital, and had an undoubted second attack; this was in 1901–2. Second attacks of typhus and chicken-pox were rare, but certainly did occur. Dr. BRADLEY said that, as a school doctor, he would like to refer to an epidemic of sore throat from which they had isolated streptococci appearing to be all of the same type. It ran a long course, and then died out. He suggested that it was possible for a new infection to antagonize a previous epidemic.

SECTION OF PUBLIC HEALTH (INCLUDING TUBERCULOSIS AND OCCUPATIONAL DISEASES)

Friday, July 24th

PROBLEM OF THE CHILD IN THE TUBERCULOUS HOUSEHOLD

The third session of this Section opened with Sir GEORGE BUCHANAN in the chair.

Dr. R. C. WINGFIELD (Frimley), in the opening paper, referred to the financial burden and the legislative steps necessarily associated with any further efforts to diminish the incidence of tuberculosis. There were many conflicting opinions as to how these children should be dealt with, and the view-points of clinical and preventive medicine were often essentially different. The problem could be stated as four questions. (1) What was the relation, in time and in intensity, of the incidence of infection among contact children to that among the general child population? (2) Did the "contact child" run greater risks of immediate sickness and death from tuberculosis than the average child? (3) Was the contact child, similarly, exposed to a greater risk of future sickness or death from tuberculosis? (4) Did the contact child constitute an immediate danger to the community? Dr. Wingfield quoted figures to show that the incidence of infection was much higher among contact children, occurring earlier in them, and almost reaching its highest point during the first five years of life. The death rate from tuberculosis (and therefore presumably the incidence of clinically recognizable infection) was definitely higher among contact children. The risk was greatest with the youngest children, and the danger was probably that of repeated infections. As regards the risk of future sickness or death from tuberculosis the position of the contact child was more debatable. Infection in childhood certainly exerted a protective influence, but there was no evidence to show that the extremely early infection, which was the prominent feature of childhood exposure, exerted any influence on the incidence of adult disease. It might, however, be concerned in causing adolescent tuberculosis. The contact child who was not actually suffering from tuberculosis did not constitute a public danger, so far as was known at present; but the question could not be regarded as finally settled. Dr. Wingfield then offered some constructive suggestions. The general practitioner should pay more attention to the hygiene of the home. The danger to children was not so much exposure as continuous and intimate exposure. Tuberculin should be more extensively used as a diagnostic test. Particular care was necessary when adolescence was reached, and *x*-ray examinations should be made, for the adolescent with open and obvious tuberculosis was a rather hopeless problem. B.C.G. immunization was useful to tide over the dangerous period of infantile contact, in conjunction with methods of preventing continuous mass exposure; but the protection was admittedly short-lived. Desensitization by tuberculin injections might also be tried.

Sir GEORGE BUCHANAN remarked that Dr. Wingfield's paper had afforded another excellent example of what might be termed "stocktaking" in public health. present position and future possibilities had been cle outlined. Dr. Wingfield's method of formulating pre questions and summarizing the lines of reply was part larly commendable in this connexion.

Dr. F. R. G. HEAF thought that a clear distinc between the various types of lesions in childhood required before definite conclusions could be reacl Infection must be distinguished from active disease. distinction must also be recognized between cases which active infection was confined to the lympha and those which were definite instances of pulmon tuberculosis. In speaking of "survival infection," Dr. Wingfield mean merely an apparently healthy c with a positive Mantoux reaction, or a patient who had definite clinical symptoms of adenitis or pulmon tuberculosis? In the first two types a degree of munity was certainly conferred, but in cases of pulmon tuberculosis the work of Opie and McPhedran seemed indicate that, if a pulmonary lesion healed in childh —not so rare an occurrence as once thought—it wo probably break down eventually in early adult life. sudden increase in the number of deaths from pulmon tuberculosis after the age of 15, and the frequency w which healed infantile lesions were found in these ca indicated that any immunity acquired in childhood disappeared, and it might be that a negative ph had been established. It was also significant that cases of adult pulmonary tuberculosis there was rarely evidence or history of cervical adenitis, and vice ver it was usual to find cases of cervical adenitis with pulmonary lesion. Tuberculosis in its early stages essentially a disease of the lymphatics; so long as infection was limited to that system it might be trea successfully and relapse prevented. In contacts t first line of defence was only too frequently broken do by repeated fresh infections, which the resistance of body was unable to withstand. The incidence amo contact children was much higher than among n contact ones. At the age of 2, excluding those child who had received such a massive infection as to prod general infection, over 50 per cent. were in a state lymphatic infection which could be controlled arrested. Provided that these children could be protec from further infection they should enjoy as good hea as the non-contact child, and possess a certain deg of immunity. But the childhood infection must be c mild character confined to the lymphatics, if it was go to exert a protective influence against adult infection.

The problem therefore resolved itself into prevent the contact child becoming re-infected. The morta figures varied with the conditions of life. In Aus there was the appalling figure of 40 per cent., while Papworth Colony there had been no deaths recorded fr tuberculosis among the children of the colonists. Betw these extremes could be found all degrees. The obvi course was to remove the source of infection or to rem the child from the source of infection. The former volved strict adherence to all the rules of hygiene i suitable environment by the parents, a condition wh could only be carried out in a colony administered on lines of Papworth. The other meant taking the ch away from its parents to suitable conditions until was at least 6 or 7 years of age, when it should h as good chances as the non-contact case. Enough st had not been laid upon the deprivations present in tuberculous home, and the far-reaching effects these m have on the health of the child or children. Wingfield had given the impression that he was not in favour of harsh interference, but that he would inclined to leave it to Nature, who was slowly find her own solution; but it was surely right to assist

the struggle. Social conditions had resulted in the universality of the infection, and it was a duty to prevent the disastrous results due to neglect. No attempt should be made to lower the incidence of the infection; surely it was better for a child living in a city to have a moderate positive Mantoux reaction. The speaker said that he looked forward to the day when children would be either immunized by the living virus or desensitized with tuberculin injections. All contact children should be subjected to a periodic Mantoux test, and as soon as they became reactors they should be removed from further infection until 6 or 7 years of age, when they might be allowed to return home if the conditions had been made suitable, and the parents were capable of preventing re-infection. Under this system the children would have every chance of developing both physically and mentally, and would escape the privations and anxieties which were almost always present in a tuberculous home. It was important to differentiate between treatment and segregation; the former required skilled medical attention, while the latter only needed disciplined institutions or homes conducted by suitable persons and subject to medical inspection. The outskirts of the town in which the parents were living was probably the best situation; the children would grow up immunized to an urban atmosphere in which they would probably have to live all their lives. The difficulty of removing children from their parents would lessen and finally disappear by education and propaganda.

The present solution of the problem, therefore, could be found by (1) performing Mantoux tests on all children in tuberculous homes; (2) when positive, removing the children to properly conducted homes under medical supervision or to institutions for treatment; and (3) education of the public, particularly those suffering from tuberculosis. On these lines many thousands of lives could be saved. The initial expense might be considerable, but not more than that at present expended on trying to patch up the many cases of active tuberculosis in children whose resistance had been broken down by repeated infection, and the adolescent cases which could be traced to a pulmonary infection in childhood.

Dr. H. B. GIBBINS (Eastbourne) thought contacts were classifiable into three groups: (1) contacts living in home with open cases; (2) in contact with non-infective open cases; and (3) in contact with closed cases, as, for example, hip-joint disease. He was rather surprised to hear that infection was not to be avoided. Mass infection should be remembered as well as continuous exposure. Patients in sanatoriums should be taught more systematically as regards this. Dr. L. P. LOCKHART (Nottingham) feared there was a grave danger of condemning the contact child to the less hopeful environments from the economic point of view. A definite stigma was now attached to the child who had been to the open-air school, as regards subsequent employment. In many factories the conditions were quite good, and similarly in other indoor industries. He asked whether Dr. Wingfield approved making more use of industrial medical officers.

Dr. WINGFIELD, replying, said that Dr. Heaf's reference to pulmonary lymphatics was a very practical point as regards adolescent disease. Victimization of adolescents as regards employment was a serious matter. The classification of contacts had been tried at Brompton, and certain statistical conclusions had been reached. The speaker agreed as to the value of indoor work for tuberculous patients. Industrial medical officers could render valuable assistance.

ACUTE TONSILLITIS AND SOME OF ITS SEQUELS

A joint paper by Drs. J. ALISON GLOVER and F. GRIFFITH, describing epidemiological and bacteriological observations on acute tonsillitis and some of its sequels, was read by Dr. Glover. Epidemic tonsillitis had been found to be one of the most common causes of invalidity in boarding schools; it was due to members of the haemolytic *Streptococcus pyogenes* group. Throat infection with these organisms presented various clinical pictures. These included the symptomless infection, or *healthy carrier state*; *tonsillitis*; *febricula*, *feverish* catarrh, or pharyngitis, without noticeable soreness of the throat; and scarlet fever. Any of the three last conditions might be followed by otitis media or acute rheumatism. Many serologically different types of haemolytic streptococci might cause scarlet fever, but certain types predominated; in 30 per cent. of the cases strains forming a group of heterogeneous types were concerned. Epidemic tonsillitis without rash was generally attributable to such heterogeneous organisms; these caused scarlet fever when their toxigenic powers were sufficiently high to overcome the antitoxic immunity of the person attacked. There was some evidence that the two most common types in scarlet fever were not invariably of high toxigenicity. In any epidemic of scarlet fever there were concurrent cases of tonsillitis and mild pharyngitis, and numbers of healthy carriers would be found, all yielding the same type of streptococcus as the scarlatinal cases. These unexpected sources of infection constituted one of the most difficult problems in the control of scarlet fever. Epidemics of tonsillitis, or the occurrence of "dropping" cases of scarlet fever, and perhaps of otitis media in schools, were generally associated with a high carrier rate of haemolytic streptococci. Epidemics of measles and influenza, even in good hygienic conditions, increased the spread of haemolytic streptococci, which were the chief cause of serious complications in these diseases. Epidemics of tonsillitis and the prevalence of high carrier rates of haemolytic streptococci sometimes indicated the existence of bad environmental conditions, such as crowded or deficiently ventilated dormitories. Adequate spacing of beds and the prevention of crowding in classrooms were important factors in preventing the spread of infection. Dr. Glover showed slides to illustrate various statistical conclusions which had been reached in respect of the epidemiology of these streptococcal infections.

Dr. E. H. R. HARRIES (Birmingham) said that the same sort of cases were seen in fever hospitals, and the same conclusions were deducible. The percentage of positive Dick reactors in schools tested had always been very high. Nurses in scarlet fever wards developed simple tonsillitis. This condition was undoubtedly often the cause of outbreaks, in which the haemolytic streptococcus was certainly concerned. Dr. MONCKTON COPEMAN cited similar conclusions reached in the past when bacteriology was in a more primitive condition and the haemolytic characteristic of certain streptococci could not be demonstrated. Professor Klein had been the pioneer in this field, the value of whose work could not be overestimated. The speaker wondered whether these different streptococcal types might have a common origin, and the serological changes in them be due to alterations in environment. Dr. R. ASHLEIGH GLEGG (Lewes) concluded that the proper spacing of dormitory beds was a serious practical matter. He had obtained evidence showing that scarlatinal infection disseminated by milk, though the primary cases were sometimes mild, had led to such grave complications as erysipelas and nephritis. Cases of sore throat occurring in workers on dairy farms should be notifiable, and when there were similar occurrences in the general community the milk supply of the patients should be traced by the general practitioner.

Dr. R. H. WILSHAW (Worthing), speaking about the high percentage of tonsillectomies in which otitis media

was said to develop subsequently, thought that the incidence of disease had been diminished rather than increased by generalizing this procedure. Dormitories ought to be arranged with more cubic space for each inmate. Dr. W. H. BRADLEY (Bath) agreed that the tonsillectomy percentage was high, and that no decrease in naso-pharyngeal disease incidence had ensued. Droplet infection was the essential factor in this problem. Mouth-to-mouth infection rather than space considerations were concerned in some cases of epidemic streptococcal outbreaks. Dr. J. TERTIUS CLARKE (Harrow) asked whether rheumatic fever in schools was more common than had been thought. He also inquired about the conditions in Malaya, where scarlet fever did not occur, and, when introduced, did not spread.

Dr. GLOVER replied that haemolytic streptococci did not seem to occur near the Equator. Diphtheria was curiously rare in public schools. As regards standards of space in dormitories, that of the Board of Education —3 feet between the beds—was advisable and probably safe, even in cases of coughing. Prevention of disease in haemolytic streptococcal cases was very largely a matter of space.

Dr. W. E. PORTER (Eastbourne), proposing a vote of thanks to Sir George Buchanan for his continued presence on each of the three days, said that the Ministry of Health was very well provided now with facilities for acquiring information of the highest practical importance. Even in Eastbourne there were far too many facilities, however, for investigating haemolytic streptococci. Mental improvement was one of the most striking benefits conferred by tonsillectomy, and fully justified its practice. The increasingly common open bedroom window was a gratifying sign of the present progressive times, and had much improved the general health. As a member of the town council he reiterated the pleasure felt by Eastbourne at the visit to it of the largest congress hitherto.

Sir GEORGE BUCHANAN replied that he had been at first almost appalled at the number and variety of topics raised during the three days, but the results had been most happy. The papers had been excellent in themselves, and had all interlocked most usefully ; the Section had been of the greatest value, and must have been one of the best ever arranged. The excellent work of the secretaries, Drs. Gibbins and Massey, had been very largely responsible for this, and the size of the various audiences had been most gratifying.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

Friday, July 24th

THE PROGNOSIS IN GENERAL PARALYSIS

With the President of the Section, Sir JAMES PURVES-STEWART, in the chair, Dr. W. A. CALDWELL read a paper entitled, "A survey of probable prognostic factors in the treatment of general paralysis." He said that the data on which his paper was based had been obtained from observations made on seven or eight hundred patients who, while under certificate in the London County Council mental hospitals, had received treatment by methods such as malaria, relapsing fever, sulfosin and tryparsamide, or a combination of some of these, together with subsidiary treatment by novarsenobenzene and other arsenical substances. As regards sex, the incidence of neuro-syphilis in women was only one-third of that in men, although the nervous systems of both (as shown by the relative percentages of cerebro-spinal fluid abnormality) were invaded with equal frequency in the early stages of syphilis. The differences were greater in women who had one or more pregnancies ; the greater the number of pregnancies, the lower was the incidence of neuro-syphilis. In analysis of the figures showed that a previous pregnan the chances of a successful remission of the regards age, excluding juvenile paretics, it was the younger the patient was the better was th This was true in a restricted sense, since w with certifiable mental disease one was usually the patient reached a state of remission good justify his discharge from hospital, and suffi longed to allow him to remain out indefinitely return to the normal was not demanded. If c the first criterion, age was not of such param tance, for some patients as old as 56 remitted ment, while others over the age of 60 definitel Of discharged patients who could be r economically satisfactory 71 per cent. were un of 40. This age factor, however, was of lit assessing the chances of life in a treated pa the cases under consideration the highest rel rate was found in patients between the ages o Different types of general paralysis were als vary *in their response to treatment*. The grandiose paretic still appeared to be the m type, and at the same time gave the high *discharge rate ; this was very closely follo* manic type. At the other extremes came th and the juvenile cases. There was a definite t *early treatment—treatment* begun two to after the first manifestation of general paraly better results, since not only was the discharg in the earlier months, but the unimproved c to increase proportionately as time elapsed. still the most successful pyretic agent, for (excepting sulfosin and allied sulphur prepa introduction of which was too recent for a co ment of their value to be made) were uncertai their production of any reaction, or, hav effective, were uncontrollable in their course. cent. better result was obtained if the malaria up by a course of novarsenobenzene. The pa cussed by Dr. F. R. P. TAYLOR (Hellingl WORSTER-DROUGHT, and the PRESIDENT.

EXOPHTHALMOS OF CENTRAL ORIGIN

Dr. W. RUSSELL BRAIN said that by exop central origin he implied exophthalmos occurr ciation with signs clearly pointing to an orga the central nervous system. The following clin were important. Such exophthalmos might b with supranuclear ocular palsies, especially wi of conjugate vertical movements and c external ophthalmoplegias ; or internal *ophtha* sluggish pupillary reactions or even the Argyl pupil. The exophthalmos might be unilateral or unequal on the two sides. It might b with lid retraction or with ptosis, either unilateral, equal or unequal. It might occ without enlargement of the thyroid gland, a be associated with disturbance of the sugar The lesions associated with exophthalmos logically varied, and often obscure. Encephaliti usually with Parkinsonism, was responsible number. Several patients had a high bloo although in only one case of Dr. Brain's serie any evidence that the lesion was vascular. S only be distinguished as nuclear ophthalm unknown origin. The most important single that in which ophthalmoplegia was associated w enlargement ; some of these cases had been d myasthenia gravis associated with exophthal Dr. Brain also gave details of the cases he ha illustrating them by lantern slides. The pap cussed by the PRESIDENT and Dr. D. MCALPI

PSYCHIC PAIN IN THE PSYCHOSES

Dr. HENRY DEVINE, in a paper on psychic pain in the psychoses, said that, taking the psychoses as a whole, he considered that external stresses played a relatively small part in their development. Financial disaster, the loss of someone loved, persistent domestic stress, and impaired social esteem might reasonably be expected to affect the psychic equilibrium; but, generally speaking, they did not have this effect. They might, and often did, bring about enduring psychic pain and tended to diminish efficiency. When a psychosis developed under severe stress some pre-existing abnormal sensitivity, or some inadequacy in meeting the demands of everyday life, would probably be revealed in the history. A negative history of recent trauma generally excluded the possibility that external events might have taken part in the causation of a psychosis. In all cases it was necessary to make extensive inquiries into the past, with a view to discovering the extent to which the symptoms could be traced to subtle environmental influences which had affected the instinctive emotional life. One could scarcely fail, however, to be driven to the conclusion that there was some pre-disposition in the subjects to a psychosis which rendered them peculiarly liable to succumb to the inevitable stresses of life. It was Dr. Devine's purpose to consider in their general terms the nature of the defects in these patients which favoured the development of a mental illness. Psychic pain or discomfort—pure feeling without cognition—was an essential primordial, indispensable, and innate element in the process of life. Discomfort, and not pleasure, was the primary stimulus of vital capacity. Pleasure was essentially a negative stimulus. Even supposing that external agents played an important part in the causation of the psychoses, little could be done in preventing these illnesses. It was true that psychotherapy often resolved itself into the provision of an artificial environment where the patient could be relieved of the inevitable tension of daily life, but this could not be described as curative treatment. The ideal therapeutic aim was to disentangle the inner life of the patient and to enable him to meet the difficulties of life with confidence, courage, and good humour. Dr. Devine then proceeded to discuss the psychology of the schizophrenic, comparing the thought-activity of these patients with the normal dream-activity. What was seen in these patients was not the deterioration of the more recently acquired functions, but rather of the oldest and less essential functions—namely, those of instinct and feeling. It had to be recognized that intellect, as distinguished from feeling and emotion, was not an indispensable element of life. The paper was discussed by Dr. H. CRICHTON-MILLER.

ENCEPHALOGRAPHY AND VENTRICULOGRAPHY

Dr. H. COHEN (Liverpool) showed cinematograph films illustrating (1) the technique of the replacement of cerebro-spinal fluid in the subarachnoid system and ventricles by air introduced by the lumbar route (encephalography); (2) the technique of ventricular puncture, and the replacement of the cerebro-spinal fluid therein by air; and (3) an operation for the removal of a large parietal cerebral tumour, which proved to be a tuberculoma. He also showed a series of lantern slides demonstrating the results of radiographical examination of the head following the subarachnoid and intraventricular introduction of air (encephalography and ventriculography). During the course of his remarks Dr. Cohen said that in 74 per cent. of cases of cerebral tumours no *x*-ray evidence of their presence could be obtained, apart from ventriculography; hence this procedure was of great value, not only in the lateralization, but also in the localization of such tumours.

The President, Sir JAMES PURVES-STEWART, also showed an interesting series of slides illustrating the results of encephalography in frontal tumour, parietal subdural haematoma, temporal lobe tumour, growth in the lateral ventricle, mid-brain tumour, and tuberose sclerosis.

SECTION OF OTO-RHINO-LARYNGOLOGY

Thursday, July 23rd

VERTIGO

The opening paper at the second day's proceedings was read by Mr. F. W. WATKYN-THOMAS, on the subject of vertigo. Confining himself to vertigo associated with aural suppuration, he said that three principal groups of cases were to be distinguished. These were: (1) cases in which the labyrinth wall was intact; (2) cases in which the labyrinth wall had yielded to infection to a great or less degree—the labyrinthites; (3) cases in which infection had reached the posterior fossa—cerebellar abscess and retro-petrous abscess. The usual classification of the different forms of labyrinthitis was admittedly faulty, especially in the inaccuracy of the terms employed, but it usefully emphasized important clinical distinctions. The three principal varieties were: circumscribed labyrinthitis, serous labyrinthitis, and diffuse suppurative labyrinthitis, which might be either latent or manifest. In suppurative labyrinthitis the aim of surgery was not to alleviate the vertigo, but to insure against meningitis. It was now generally admitted that in the first enthusiasm for labyrinthine surgery far too many labyrinth operations had been done, but, on the other hand, he thought that the reaction had now gone too far, and the belief that no labyrinth operation should be done until meningeal signs appeared was responsible for dangerous delays.

Mr. EDWARD D. D. DAVIS read a paper founded on the study of seventy-two cases of vertigo seen by him, in which thorough investigations had been made. Of these cases three were due to traumatism, three to acute otitis media, six to acute aural suppuration or exacerbation of a chronic suppuration, twelve to chronic aural suppuration, fourteen to secondary sclerosis after healed suppuration, two to Eustachian obstruction, thirteen to otosclerosis, two to cerebellar abscess, one to tabes, three to disseminated sclerosis, three to general intestinal and circulatory disorders, and in ten cases the cause of the vertigo was unknown. Some of the cases of otosclerosis showed a distinctly low blood pressure, but with this exception the blood pressure was normal, and there were no cases of high blood pressure.

Sir JAMES DUNDAS-GRANT's experience was more with chronic than with acute cases. Ménière's disease was a favourite diagnosis with physicians, but the vertigo might often be due to other conditions, such as arterio-sclerosis, epilepsy, or cerebellar tumour. He was convinced of the value of small doses of quinine in the treatment of labyrinthine vertigo; so much so, that it was of value in diagnosing labyrinthine from other conditions. In his opinion the quinine lowered the sensibility of the sound side more nearly to that of the diseased side. Mr. MUSGRAVE WOODMAN (Birmingham) had performed the Portmann operation of opening the endolymphatic duct in seven cases; six patients had been entirely relieved of their symptoms, which in one of them, however, had recurred in three months. The operation should be limited to cases that were not relieved by simple treatment. It was quite a safe operation in skilled hands, and had a very short convalescence. Mr. HERBERT TILLEY said that, in contrast with Mr. Davis, he was a firm believer in the part which Eustachian obstruction played as a factor in some cases of vertigo, and instanced a very striking example which occurred in a medical colleague. The patient "staggered" into his consulting room, but a few moments afterwards, and as a result of inflation, he walked out without the slightest trouble, and drove

his own car home. He had often wondered if many of the fatalities which occurred during open-air bathing, and which coroners' verdicts ascribed to cramp, might not have been due to cold water entering the middle ear through a perforation, thus inducing a caloric reaction and giddiness. Vertigo coming on suddenly in deep water would obviously be a most paralysing accident; whereas cramp in one or both legs would not cause a bather to sink or render it impossible for him to use his arms and hands to keep on the surface for a few moments till help was available.

Dr. Dan McKenzie said that if there was such a Section of the British Medical Association as a General Practice Section, vertigo or giddiness would surely be one of the most frequently and urgently discussed subjects, for it was one of the most common ailments in general practice. He insisted on the term Ménière's "disease," and not "syndrome," or the other terms that were being used; for if the Ménière group of symptoms was not a disease he did not know what a disease was. Mr. J. F. O'Malley said that the textbook classification of vertigo was still unsatisfactory, symptoms having been mixed up with the real causes of the disease. Mr. Lowndes Yates raised the point of compensation in vertigo; when one labyrinth died the other took on its functions. Some cases could be cured by simple exercises to establish compensation: making patients turn one or the other direction every day, or making them walk blindfold, were simple examples. Mr. T. B. Jobson (Guildford) mentioned post-traumatic cases, and asked how the pathology was to be explained. Mr. Mollison, the President, mentioned cases in which there were sensitive spots on the external canal, without any fistula and in the presence of a dry mastoid cavity; such cases were relieved by painting the spots with a caustic. Like Mr. Tilley, he was concerned with the importance of Eustachian blockage in causing vertigo.

Mr. Watkyn-Thomas, in reply, said he had seen one case of leukaemia in which there was bilateral labyrinthine obstruction, and in this case there were practically no labyrinthine symptoms. He agreed that Eustachian obstruction was a factor, but he thought there was usually another factor as well, such as an impacted wisdom tooth or a sinus suppuration. Relief of Eustachian obstruction relieved the general waterlogging. The psychological element was also important. He thought this was helped by exercises such as Mr. Yates had mentioned.

Acute and Subacute Otitis Media

With Mr. J. B. Horgan, Vice-President, in the chair, Mr. H. V. Forster (Liverpool) read a paper on the diagnosis and treatment of acute otitis media. Mr. Forster said that of several microbic invaders of the middle ear a haemolytic streptococcus was the most common, being found in from 73 to 90 per cent. of cases examined. Among the causes of acute otitis media the common cold took an important place, as well as influenza and sinus disease awakened by the attack. Of the acute specific fevers, scarlet fever and measles predominated as invaders of the middle-ear cleft, and they stood supreme as sources of lasting and permanent damage. Pain was the symptom that called most frequently for an early incision of the membrana tympani, but one objection to early paracentesis tympani was the difficulty of the operation; the description of the proceeding sounded easy enough, but in actual practice, to carry it out accurately was not so easy. He considered that a curved incision across the lower quadrants was the best.

Mr. A. Lowndes Yates followed with a paper on subacute otitis media, which, he said, differed from the acute variety in that the Eustachian tube, obstructed in the former, was partially patent, and the pus drained down it; the acuity of the inflammation was generally in proportion to the degree of obstruction of the tube. In children, attention should be directed to the nasopharynx, and any adenoids removed, while sinuses suspected of infection should be washed out. An increasing deafness after paracentesis warranted the performance of a mastoid operation, particularly if the deafness were bilateral. In adults there were two varieties of case. In one the subacute condition was of recent origin, and similar in all respects to that of children; in the other the inflammation was maintained, and if undiagnosed—as frequently it was in its early stages—led to irremediable deafness.

Mr. J. F. O'Malley read a paper on the ear complications of influenza, referring to a series of cases he had encountered recently. In addition to surgical treatment, he had found injections of S.U.P. 36 to be most useful in these cases.

Mr. Herbert Tilley said that for many years he had advocated early paracentesis of an inflamed membrana tympani associated with symptoms of infection of the middle-ear cleft. If due care were taken to sterilize the external meatus as far as possible, only benefit would accrue from providing drainage from the tympanic cavity. Furthermore, he strongly advocated the application of the suction speculum immediately after the membrane had been incised, and until blood unmixed with pus issued from the artificial perforation. A lightly packed wick of gauze was then passed down to the drum-head; it was removed after a few hours for irrigation of the meatus, and again gentle suction with the speculum was carried out. Sphenoidal sinus suppuration was the only form of sinus infection which he had known to cause earache, and this was in the nature of a referred otalgia. Reference had been made to blebs of blood on the tympanic membrane or the deep meatal walls, and in his experience these were nearly always in cases of influenzal origin. The difficulty in diagnosis between meatal furuncle and mastoid infection should not often occur if they bore in mind that in the former the patient often heard well and passive movement of the pinna caused considerable pain, while, in mastoid inflammation, the patient was nearly always deaf on the same side, and the pinna could be handled freely without pain. Dr. Dan McKenzie insisted on the value of paracentesis in these cases, but said that in his opinion the incision must begin at the top of the drum and be carried straight down. Mr. Scott Stevenson said that he hoped Mr. Forster would not discourage practitioners from doing paracentesis more frequently by emphasizing the difficulties of that little operation. Many of the alleged difficulties would disappear if an electrically lit ear speculum were used, with a small magnifying glass attached, and if the operator employed a bayonet-shaped knife, and not one of the angled knives Mr. Forster had exhibited.

Mr. Watkyn-Thomas commended the clearness with which Mr. Lowndes Yates had defined the different types in the somewhat obscure condition of subacute otitis media.

SECTION OF HYDROLOGY AND CLIMATOLOGY

Friday, July 24th

Treatment of Arthritis

With Dr. Percy Lewis (Vice-President) in the chair, Dr. C. W. Buckley (Buxton) read a paper on the control and treatment of arthritis. He pointed out certain errors in living and developmental defects of environment which remained fairly constant in most cases of arthritis, and which indicated certain lines of treatment. He said that there were essential analogies between tuberculosis and chronic arthritis, and suggested that treatment in these diseases ought to be arranged on similar lines, with or without the addition of physical methods in the latter

case. The rheumatic group was of greater importance from the industrial point of view; there were certain broad lines on which the successful campaign against rheumatism should be carried out clinically. The speaker then classified the joint manifestations of rheumatism, and pointed out that there was a large group of cases in which heat, far from proving beneficial, was actually harmful. He stressed the importance of diet in rheumatism, casting ridicule on certain traditional beliefs, making some stimulating references to the endocrine system and its relation to the etiology and treatment of these diseases. He ended on a note of warning with regard to the indiscriminate use of vaccines in rheumatism, and of letting their dosage be fixed in the laboratory rather than at the bedside.

Dr. W. S. C. Copeman advocated the sanatorium treatment of the rheumatic diseases, and proposed a scheme for this, similar to one used in Russia, whereby the patient continued at his work in the day-time and had treatment at night and over the week-ends. The discipline, self education, and encouragement were, as in the case of tuberculous patients, of special value in such a plan. He also referred to idiosyncracies in diet shown by certain rheumatic patients. Dr. Delicati suggested that there was a nervous origin for some cases of rheumatoid arthritis, and referred to work in America which supported the view that the condition might be due to a lack of balance between the autonomic and endocrine systems. He briefly outlined two types of case in which he suggested that one or the other system predominated. Dr. Hallowes (Torquay) stressed the need for the early recognition of cases of arthritis, and mentioned the rarefaction of bone observed in a large number of cases. He referred to the unsuitability of some cases of these diseases being treated at sea-level, but maintained that each patient was a law to himself in this and dietetic matters. Mr. Harman Taylor (Liverpool) mentioned the important role of rest and exercise in the treatment of arthritis, and the need for a wide consideration of the whole subject. Drs. Wilshaw and Edgecombe (Harrogate) also spoke, and Dr. Buckley replied.

Hyperpiesia

Drs. Bain and Edgecombe (Harrogate) read papers on hyperpiesia from the etiological and pathological points of view, discussing the therapeutic aspect and prognosis, with especial reference to the place of physical medicine in the treatment of these cases. They gave an excellent summary of the whole subject, and quoted illustrative cases which had been followed for a considerable number of years. The connexion between the pathology of the bowel and the onset of hyperpiesia was strikingly demonstrated in several of these patients, and a good case for hydrotherapy was made by the blood-pressure readings before and after courses of treatment. This treatment, they said, was palliative only, but was in advance of any other methods used, the effects being, in many cases, well sustained for months or years. The necessity for very careful treatment in the case of patients with advanced disease was stressed, and the contraindications for further treatment clearly set out. Dr. Percy Lewis (Folkestone) advocated the judicious use of drugs such as iodine. Dr. Buckley quoted a case which showed the retarding effect of physical treatment on the progress of hyperpiesis. Dr Payne (Darlington) remarked on the beneficial effect of compulsory retirement of a business man with hyperpiesia. Dr. Fortescue Fox (President) gave his opinion that waves of high blood pressure occurred periodically at different periods of life, and that this explained remissions occurring naturally—especially in later life and in subthyroidic patients. He mentioned the value of venesection in early cases. Dr. Edgecombe, in reply, said that he agreed with Dr. Fox's theory of periodic waves in women, but doubted this occurrence in men. He mentioned the variable association of hyperpiesia with obesity.

Therapeutic Pools

Dr. R. G. Gordon (Bath) read a paper on the use of therapeutic pools, dealing first with the historical aspect and going on to the modern use of this method of physical treatment, which he considered to be not sufficiently used. He showed lantern slides illustrating his methods of dealing with the after-results of poliomyelitis in children in the Orthopaedic Hospital at Bath. He was of the opinion that more could be done by this method than by any other. The physiological effects of this treatment included an increase in body temperature, metabolism, elimination of toxins, diaphoresis, dilatation and increased vascularity of the capillaries in the diseased limb, and in the elimination of the inertia and force due to gravity, with consequent relief of spasm and gradual increase in voluntary movement and muscular power. He referred briefly to other indications for this type of treatment, notably arthritis of rheumatic and other origin and congenital hip disease in children. Dr. Fortescue Fox remarked on the growing use of the therapeutic pool in orthopaedic hospitals in the United States of America, and referred to its use also in mental hospitals.

THIRD INTERNATIONAL CONGRESS OF RADIOLOGY

The third International Congress of Radiology was held in Paris from July 26th to 31st, with Dr. Antoine Béclère as president. It will be remembered that these congresses owe their initiation to the late Dr. Robert Knox. More than 1,300 delegates were present from over thirty countries, for whom a festival luncheon was arranged by the City and University of Paris on the first day. On July 27th the President of the Republic was present at the official opening, when Dr. Béclère delivered an address.

The President expressed his regret that many German radiologists had been prevented from attending owing to the present economic crisis, but the German Roentgen Society was nevertheless represented by three official delegates. He then traced the steps in development of medical radiology, and commented on the part it might play in the campaign against cancer. Although more than one country was notable for its radiological discoverers and inventors, the whole science was international, being directed solely to the revealing of truth and the amelioration of human suffering. Medical science rose above the sphere of politics, and united all in its discoveries as well as in its quests. The International Congress would promote this deeper comradeship, and was, perhaps, a foreshadowing of a state which would prevail eventually among all nations in their mutual relations.

At the conclusion of his address, Dr. Béclère was presented by Professor Woodburn Morison with the diploma of honorary fellowship on behalf of the Royal Society of Medicine; he also received a diploma from the University of Zurich, a chairman's mallet from the Society of American radiologists, a mallet from the Swedish Society of Radiology, and a gold chain from the British Institute of Radiology.

The Campaign Against Cancer

After the president's speech Professor Forssell of Stockholm, who had presided over the last congress, delivered an address on the social campaign against cancer, and suggested lines on which better progress could be made. He pleaded for such a co-ordination in this respect as had been achieved in other branches of medical science. The study of its biology and pathological anatomy, as

well as its experimental side, should be a part of the work of the already existing general medical institutions ; the study of the diagnostic, clinical, and therapeutical aspects should be entrusted, on the contrary, to special clinics and laboratories. The establishment of great cancer institutes for research was only possible in the chief world centres of science, but the subject was one demanding co-operative international work. The practical application of the discoveries made was a national responsibility, economy and efficiency having to be borne in mind always when planning any special steps. The objective was to assure to all sufferers from cancer the best treatment possible, irrespective of their wealth or poverty. The cause of cancer being as yet unknown, very little was possible so far as regards preventing its incidence. An intimate association of surgery and radiotherapy was still necessary in treating this disease, and Professor Forssell gave statistical details to illustrate the way in which these two lines of treatment could be most efficacious. He concluded that about 90 per cent. of cancer cases needed some other treatment than pure surgery, and that radiotherapy had a very distinct place to take in this respect. Just as the surgical clinic had won recognition in the last century as a great therapeutical asset, so now must the radiotherapeutical clinic take a similar place. It would be a centre for organization ; around it would be grouped the necessary adjuncts for treatment, and for keeping it in close touch with the other related branches of medicine. Such an organization would naturally vary in detail in different countries, but as a general rule it was clear that, unlike surgery, radiotherapy could not be decentralized, but would necessarily be limited to a definite number of centres, placed in definitely delimited areas of each country. Each radiotherapy clinic should have fifty beds, 4 to 5 grams of radium, and the necessary *x*-ray equipment. Pathological and radiological laboratories would be attached to each of these clinics ; arrangements would be made for statistical investigations, and for following up the patients after treatment. In view of the continued progress in radiotherapy, it was obvious that such centres should be closely linked up, and facilities be available for the instruction of students. Public instruction on the importance of early diagnosis would have to be extended without arousing any undue alarm. This could best be done by means of general practitioners transmitting their knowledge, with special emphasis on the earliest signs of cancer, and the need for expert advice. We are informed that this speech will be published in the *Journal de Radiologie et d'Électrologie.*

OTHER ASPECTS OF RADIOTHERAPY

Dr. J. E. A. LYNHAM (London), discussing the pre-operative and post-operative treatment of cancer of the breast by irradiation, said that the whole question turned on recurrence, for comparatively few died of the primary disease. It was in the treatment of inoperable metastases that both radium and *x* rays had first proved their value, and prophylactic irradiation had thus come into being. Pre-operative irradiation was now under consideration, but no final conclusion as to its value had yet been reached definitely in Great Britain. The way in which irradiation worked in relation to malignant disease was not yet understood, nor the reason why metastases might only appear after so long an interval as fifteen to twenty years. Pre-operative radiation by *x* rays was regarded as the best form ; the dose should be full, but not excessive, lest there be interference with healing. The application of *x* rays to the open wound was not regarded as satisfactory. Post-operative radiation was generally undertaken by means of the superficial application of *x* rays or of radium. There was great need for a better co-ordination of techniques and comparison of results ; in this respect the British Institute of Radiology served a most useful purpose in Great Britain, offering an example which might perhaps be followed with advantage in other countries.

Dr. L. G. COLE of New York described the technique of exploring the gastro-intestinal mucosa, and explained how the findings might be assessed in terms of health and disease. He defined four basic findings—namely, (1) the contour of the lumen of the tract ; (2) the appearance of the folds, particularly valuable in the diagnosis of ulcers of the lesser curvature and pyloric valve ; (3) the pliability of the mucosa to peristalsis—a matter requiring serial radiograms, studied stereoscopically ; and (4) the mucosal pattern, which though particularly valuable in diagnosing some of the more obscure and unimportant lesions of the mucosa and submucosa, was of less practical significance than observation of the pliability of the mucosa. Correlation of the radiological and pathological findings had been undertaken ; this had proved of great value in diagnosis, as well as in investigations into the etiology of morbid processes, their life-history, and the indications for medical and surgical treatment respectively.

Professor MILANI of Pérouse dealt with radiotherapy in its application to inflammatory conditions. Generally speaking small doses rather than large ones were favoured ; the best results were obtained in general suppurative conditions of the skin, eyes, ears, nose, and teeth ; in inflammatory conditions of the genital organs ; in similar affections of the mouth and joints ; in broncho-pulmonary conditions ; and in diseases of the central nervous system. A particular interest attached to this branch of radiotherapy, for further research into the way in which it acted on inflammatory states might elucidate the larger problem of the effects it produced on the morbid conditions generally.

Professor HAENISCH of Hamburg described the methods of examining the functional capacity of the urinary system by the use of radio-opaque substances. His paper will be published in the *Fortschritte auf dem Gebiete der Röntgenstrahlen.*

Apart from these four chief topics on which discussion proceeded, numerous independent communications were presented, under a time limit. Lantern slides were shown, and useful exhibitions of radiograms, books, and apparatus were open throughout the congress, which was held in the Sorbonne.

The official delegates from Great Britain were Dr. G. W. C. Kaye, Dr. A. E. Barclay, Dr. J. E. Lynham, Major McGrigor, and Dr. C. E. S. Phillips. Other British representatives included Mr. Thurstan Holland, who presided over the first international congress ; Mr. Cecil Rowntree, representing the British Empire Cancer Campaign ; Professor S. Russ, Medical Research Council ; Mr. Comyns Berkeley, British Radium Commission ; and Professor F. L. Hopwood. Professor Owen of Bangor was honorary secretary of the Measurements Committee. Dr. Stanley Melville, honorary secretary of the Protection Committee, was absent from the congress on account of illness. Among the British contributors to the proceedings were Dr. J. H. D. Webster (operable and borderline cases of breast cancer), Dr. S. Gilbert Scott (radiographic diagnosis of arthritis), Drs. Piney and Riach (radiological treatment of myeloid leukaemia), Dr. C. A. Robinson (pelvic diathermy for arthritis), and Dr. J. V. Sparks (pulmonary asbestosis).

H.M. Stationery Office has published a list of medical practitioners in England and Wales, approved by the Board of Control, for the purpose of making recommendations under Section 1 (3) and 5 (3) of the Mental Treatment Act, 1930.

The Water Pollution Research Board of the Department of Scientific and Industrial Research has issued a technical paper (No. 2) on a survey of the River Tees (Part I—Hydrographical), referred to in the *British Medical Journal* of July 5th, 1930. This pioneer investigation, which also includes biological and chemical sections, was started in April, 1929, with the main object of determining the amount of polluted liquid that may safely be allowed to enter a river without unduly retarding the natural processes of purification. The text of the present report is supplemented by tables, graphs, and forty-six plates. Copies may be obtained from H.M. Stationery Office, price 5s. 6d. net.

Correspondence

RETIREMENT OF DR. T. H. C. STEVENSON

SIR,—We do not wish the retirement of Dr. T. H. C. Stevenson from his official work at the General Register Office to pass without an expression of our deep regret on the event, and of our appreciation of his public services.

Of Dr. Stevenson's contributions to the scientific journals we shall say nothing, except that these would have sufficed to secure a permanent place for him in the history of statistical science. The searching and illuminating discussions of the problems of vital statistics which he has contributed to the Census reports and to the annual and decennial reports of the Registrar-General have formed noteworthy landmarks in the study of our national records. Dr. Stevenson's remarkable analysis of the data of the census fertility taken in 1911 was a *tour de force*, while the essays contributed by him to the annual reports of the Registrar-General make a wider appeal and, in our judgement, place Stevenson second only to William Farr among those public servants who have secured for England her proud position in the realm of official vital statistics. His studies of the factors of infant mortality, of the local distribution and evolution in time of mortality from tuberculosis, and of the interpretation of the statistics of cancer mortality, especially in relation to its local incidence in the human body, are further examples of immensely important medical research. Dr. Stevenson first demonstrated, upon adequate data, the contrasting rates of mortality of single and married women from cancer of the breast and reproductive organs; this and his more recent studies of the variation of cancer mortality with social status constitute probably the most important statistical contributions yet made to our knowledge of malignant disease.

In these, as in many other instances, Dr. Stevenson proved himself a worthy successor to Farr, and there has been secured that continuity of research into medico-social problems of which the Registrar-General's records form an almost unlimited storehouse. We offer this imperfect tribute to the merits of a great public servant in the hope that our readers may reward him in the way he would most value, by studying these records of first-rate investigation for themselves and be stimulated to similar inquiries based on our scantily used records.—We are, etc.,

DAWSON OF PENN.
MOYNIHAN.

THE SIGNIFICANCE OF A RAISED BLOOD PRESSURE

SIR,—Knowing as I do the high standing of Dr. John Hay in the profession, as well as outside it, I would wish to be the last to take advantage of your generosity either to "pillory him" or "to carp at" any of his statements. My sole object is to try to find out as simple a method as possible by means of which the majority of practitioners may be able to take readings of the blood pressure which can be accepted as reliable.

Dr. Hay admits that it is desirable to have a definition of blood pressure, but the one he gives by referring it to the time at which it occurs is open to the criticism of being too vague. To say that lunch will be served at one o'clock does not give us much idea of what may be expected for that meal.

I am sorry that Dr. Hay questions whether a knowledge of the equality of the diastolic pressure in all the arteries is of any clinical value. Personally I am of the opinion that a local increase of the pressure is responsible for a correspondingly local atheroma, an opinion which I think is supported by the statements of Allbutt, Marchand, and Posselt, referred to in the valuable article by Drs. Hare and Ross (*Lancet*, 1929, ii, 806).

Dr. Hay himself tells us that "*in some instances* the technique is not satisfactory, and the records, especially of the diastolic pressure, are unreliable." I think if he had said "many" instead of "some," and had italicized the word "diastolic," he would have been even more accurate, especially after the recent remarks of Dr. Maurice Shaw on the same point in your correspondence columns. The majority of teachers know how difficult it is for students to estimate accurately the diastolic pressure by the auscultatory method, and it was with the idea of simplifying the estimation that I introduced my more objective method (*British Medical Journal*, 1930, i, 242).—I am, etc.,

Swansea, Aug. 9th. G. ARBOUR STEPHENS.

SIR,—I was away on the Continent for three weeks, and this is why I am so late with my answer to Dr. W. Duncan Lawrie's letter (August 1st, p. 224). It is exactly in the early stage of essential hyperpiesis that the ophthalmoscope is of much help, especially if the red-free light is used. But one must not look for gross changes. A slight change in one or two vessels, by no means in all retinal vessels, taken in connexion with other clinical findings (heart, urine, blood pressure), will decide the diagnosis. I advise strongly a detailed description of the fundi at every examination; in time one is surprised to see a new change arising quite suddenly and unobtrusively. The earliest change would be a loss of translucency, and the appearance of fine white lines on the cross-points of the vessels. In my experience the ophthalmoscopic examination has never been negative in a patient with a diastolic pressure of 100 or more. It is impossible to answer more in a few lines, and I may refer to my three papers published in the *British Ophthalmological Journal*, starting in 1927.—I am, etc.,

London, E.1, Aug. 8th. N. PINES.

INCIDENCE OF RHEUMATISM IN BATH AND SURROUNDING AREA

SIR,—The interim report of the British Medical Association subcommittee on the incidence of rheumatic heart disease in childhood (1927–30) in Gloucestershire, Somerset, and Wilts,[1] brings out the interesting point that the disease is six times as common amongst the children of Bristol as amongst those of Bath. While no explanation of this astounding difference in the neighbouring cities can at present be advanced, it may be of interest to point out that the incidence of rheumatic affections in the latter city has apparently declined considerably of late years. Though the numbers are but small, and include adults, the following figures, culled from the annual reports of the Royal United Hospital, of admissions for chorea, rheumatism, and heart disease (including endocarditis and pericarditis) during the periods 1901–9 and 1922–29, are noteworthy as showing the considerable drop in the number of admissions since the war, and the uniformity in the numbers of annual admissions in each period.

The figures for 1910–21 are not available, but this is of little consequence, as those for the two periods mentioned serve sufficiently to demonstrate the two points referred to. It will be seen that admissions for chorea have fallen to less than a half their former number, those for rheumatism to about a third, and those for morbus

[1] *British Medical Journal Supplement*, July 18th, 1931.

cordis to rather more than half. Since the heart disease group would evidently include a number of cases having no connexion with rheumatism, the percentage fall of rheumatic heart cases is without doubt greater than this. On the other hand, into the older "rheumatism" group may have crept some cases which at a later period would be labelled "fibrositis" etc. (though the number of cases of that description would in any event be small).

The probability is, therefore, that the relative fall in both the rheumatism and heart disease groups is very much the same as in the group perhaps least open to question, that of chorea—namely, to between a half and a third of the former number.

The Royal United is a general hospital to which are admitted cases of acute illness only, from the city of Bath and surrounding country within a radius of twenty miles (except to the west); in all, a population of about 200,000. There is a special ward for children, and no children's hospital in the area.

Admissions to the Royal United Hospital

Year	Total Medical Admissions	Chorea	Rheumatism	Morbus Cordis (including Endo- and Pericarditis)	Total
1901	611	13	48	42	103
1902	669	14	44	50	108
1903	628	15	29	46	90
1904	653	16	21	51	88
1905	524	20	36	49	105
1906	713	12	22	55	99
1907	608	16	38	45	99
1908	544	13	45	41	99
1909	617	16	34	49	99
Average ...	627	15	35.2	47.5	98.8

Percentage of total admissions of the three groups: 15.7 per cent.

1922	549	5	14	29	48
1923	538	8	6	24	38
1924	580	8	17	35	60
1925	659	6	23	18	47
1926	589	7	10	25	42
1927	639	6	12	24	42
1928	565	8	11	22	41
1929	524	4	11	15	30
Average ...	580	6.5	13	24	43.5

Percentage of total admissions of the three groups: 7.5 per cent.

There is no variation in local conditions known to us which would satisfactorily account for this drop, which appears to have been a more or less sudden one during the war. The only factor which might conceivably have affected the admissions is the increased development of cottage hospital accommodation since the war in small towns in the hospital area; but it is difficult to see why this should have affected rheumatic cases to a greater extent than other medical patients, and it appears probable, especially when taken in conjunction with the sub-committee's findings, that the fall in "rheumatic" complaints in this district is a real one.—I am, etc.,

RUPERT WATERHOUSE, M.D., F.R.C.P.
Bath, Aug. 1st. Physician to the Royal United Hospital.

TUBERCULIN

SIR,—Although "the statistical picture of the incidence of infection with tubercle bacilli in children under 15," drawn for us by Dr. Dorothy Dow and Dr. Ernest Lloyd, in the main confirms the conclusions worked out some years ago in Germany by Roepke, Redeker, and other pioneers in this field, I would fain hope that the unreasonable prejudice against tuberculin as the superlative diagnostic agent in the early stages of chronic tuberculosis may give way, and allow extensive investigations upon the value of tuberculin, not only in the diagnosis of tuberculosis in children and adults, but also in the treatment of this disease. I venture to say that in years to come, unless something new and unexpected is revealed by research, tuberculin must take its place as a most valuable—indeed, as *the* most valuable—therapeutic agent we possess for the treatment of all forms of uncomplicated chronic tuberculosis in any organ, especially if it is used wisely, courageously, and even boldly in the early stages of this disease.

If Dr. Dow and Dr. Lloyd would visit my tuberculin clinic they would see from charts what can be done for otherwise hopeless forms of tuberculosis of the eye by the use of tuberculin in diagnosis and treatment; and if this can be done, and indeed watched by the naked eye, why should we not expect similar effects when the lesions are out of sight? Moreover, they would learn that success is secured without any apparent risk by very large doses—rarely less than 1 c.cm. of the strongest preparations as a final dose. He who "sees" may read.—I am, etc.,

London, W., Aug. 3rd. W. CAMAC WILKINSON.

SEBORRHOEA AND ALKALIS

SIR,—Four years ago I came across a case of "eczema" of such severity that the patient, a man aged 42, a painter by trade, contemplated suicide. The condition, which was widespread, had prevailed for eighteen years, and had caused him to be invalided out of the Army. He then spent weeks in various hospitals with little result, and was advised to tolerate the disease with *fortitude*, to be careful not to wet the skin, and to hope for the best. I ordered a daily warm bath, containing at least two pounds of sodium bicarbonate to twenty gallons of water, and a change of linen after each one. In addition, I gave him one ounce of magnesium hydrate three times a day. The condition cleared up in three days, and has never returned. The patient occasionally takes sodium carbonate or common washing-soda baths, and small doses of alkalis internally.

The next case of a similar nature was that of a girl, aged 5, sadly pock-marked, the history going back two years; but in this instance the diagnosis was "seborrhoea." The parents were well-to-do and a special nurse was provided, who, under a consultant's orders, watched the child's diet, which was almost entirely fat- and sugar-free. The patient's weight was subnormal, and baths were rarely risked. Daily warm sodium bicarbonate baths, plus one teaspoonful of magnesium hydrate by the mouth three times a day, greatly improved the condition, which finally disappeared when large quantities of citrated milk were added to the diet. The child now eats rationally, bathes normally, and has been perfectly well for over two years.

A third case, with a six months' history of seborrhoea in a girl, aged 7, met with immediate success under similar treatment.

My fourth case was not so successful. The patient, a man aged 28, diagnosis "eczema," several years' history, is a chemist by profession. He had taken an intelligent part in the various treatments tried, and on the whole was resigned to the condition, with the exception of the fear of washing. To use his own words, "I daren't have a bath unless I stink!" Daily alkali baths were greatly appreciated, and cleared the skin with the exception of a patch the size of a shilling on the dorsum of the hand, which defied all my efforts until a small dose of *x* rays was tried (one minute 2 ma. 60 Kv.) and proved successful.

In conclusion, cases of this nature suggest an underlying acidosis or an "acidæmia" which will respond to direct alkaline treatment internally and externally, and attention should be paid to underlinen, as re-infection undoubtedly occurs from this source. Abstinence from "wetting" only serves to increase the accompanying pruritus and merely adds to the patient's distress. A strict diet designed to prevent acidosis is of less value than the administration of alkalis in liberal doses. Finally, in very obstinate cases x rays are worth a trial.—I am, etc.,

London, E.C., July 29th. S. A. LEADER.

BROKEN CATHETER IN URETHRA

SIR,—With reference to the letters on this subject appearing on July 18th (p. 104) and August 1st (p. 225) I should like to point out the extreme difficulty of grasping with forceps a foreign body which closely fits the urethra, and to draw attention to another method of its removal, which I published in the *Journal* of October 27th, 1928. In the case which was there described it was impossible to grasp the piece of catheter which was fixed by muscular spasm in the membranous portion of the urethra, and the following manœuvre was successful in extracting it. The patient was placed in the left lateral position, and the index finger of the left hand introduced into the rectum, palmar surface forwards. The posterior border of the prostate was identified, and firm pressure made in the direction of the urethra while the patient squeezed the penis towards the meatus. This method of removal was immediately successful, and I think it deserves to be noted in case of similar failure to grasp a foreign body being encountered.—I am, etc.,

H. W. WEBBER, M.S., M.D. Lond.

King's Tamerton, Plymouth, Aug. 1st.

A STATEMENT FROM THE CANCER HOSPITAL (FREE)

SIR,—In view of certain statements which have appeared in the press, the authorities of the Cancer Hospital (Free), Fulham Road, wish to state that no announcement of any kind referring to cancer-producing substances has been issued from the hospital since their official report to the British Empire Cancer Campaign, which was presented at the annual meeting on July 20th last. In this report (pp. 33 to 42) no claim is made that the cancer-producing substance present in tar has been identified.—I am, etc.,

J. COURTNEY BUCHANAN, Secretary.

The Cancer Hospital (Free), Fulham Road, London, S.W., Aug. 12th.

MOTOR DRIVERS' SPECTACLES

SIR,—It is encouraging to know from the daily press that, as a community, we are improving in our driving manners, but still the tale of accidents is woefully large. A small point may therefore be worth suggesting. In how many cases has the driver of either car been wearing horn-rimmed spectacles? Although with these spectacles the vision straight ahead may accord with regulations they otherwise act as 'blinkers,' as half the vision is occluded on both sides at eye-level, and altogether at the hinges. This is often just the spot where *quick sightedness* is needed to avoid an accident. In my opinion the safest form of glasses is the pince-nez, without rims. If spectacles are used they also should have no rims, and only wire sides. I personally have tried all forms.—I am, etc.,

[illegible] H. M. HENDERSON.

Obituary

DONALD MACPHAIL, M.D., C.M., F.R.F.P.S.

Consulting Surgeon Alexandra Hospital, Coatbridge

We regret to record the death on August 2nd, of Dr. D. Macphail, late of Coatbridge. Since his retirement from practice seven years ago his health had not been good, and he became critically ill some three weeks before.

Donald Macphail had a distinguished career as a medical student at the University of Glasgow, where he graduated M.B., C.M. with honours in 1877, and proceeded M.D. four years later. In 1919 he was elected to the Fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow. After holding house appointments at the Western Infirmary, Glasgow, he was for a year resident physician at the Belvidere Hospital, he then began general practice in that city, and was appointed assistant to Sir George Macleod, at that time Regius Professor of Surgery. He subsequently became surgeon to two large ironworks at Carnbroe and Langloan, and spent the remainder of his active professional life at Coatbridge. On the opening of the Alexander Hospital in that town he was appointed one of the first surgeons, and his popularity was acknowledged on his retirement by the presentation to him of various testimonials and gifts. Among his other interests was a keen devotion to ambulance training, the advantage of which in the coal and iron industries was early appreciated by him. In association with Mr. Peter Macdonald, then at Langloan, he instituted a course of instruction, which was among the earliest, if not the first, to be undertaken in Scotland outside Glasgow. He worked for many years as a lecturer and examiner, was one of the members of the first active executive committee of St. Andrew's Association, and for twenty-eight years was secretary of the Coatbridge branch.

In his earlier years he was on the editorial staff of the *Glasgow Medical Journal*, and contributed frequently to its columns. He took an active share in the preliminary work which led to the establishment eventually of the clinical and pathological laboratory of the Western Infirmary. He was an exceptionally good pianist, and evidence of his artistic ability in another sphere persists in the form of delightful sketches illustrating some of his holiday rambles. One of his daughters, Dr. Katherine Macphail, is well known as the founder, and at present the director, of the British Hospital for Children in Belgrade.

DAVID GRANT, M.A., M.D., C.M.

Formerly Lecturer in Materia Medica, Melbourne University

On April 27th (writes our Melbourne correspondent) Dr. David Grant died at the age of 77, and on his passing there was lost a great figure in Australian medicine. But for the accident of early ill-health he might have achieved an equal distinction in a wider sphere in the land of his birth. David Grant was born in Fifeshire in 1854 and was educated at the High School, Stirling, where he was dux of the school, and at Edinburgh University, where he graduated M.A. in 1872, and was awarded the Masson Medal. In 1876 he graduated in medicine and won the Ettles Scholarship for the most distinguished student of his year. In 1876–77 he served as resident medical officer at the Royal Infirmary and had there as a fellow-resident the late Sir James Mackenzie. In 1877–78 he was resident at the Children's Hospital, Edinburgh, and in 1878–79 filled a similar post at the Royal Hospital for Consumption and Diseases of the Chest in the Isle of Wight. After doing post-graduate work in Vienna he joined the staff of the Barnes Convalescent Hospital at Chester as

resident, and also served as resident physician at the Manchester Royal Infirmary, where he had as his colleague on the surgical side Mr. Bilton Pollard, who afterwards became surgeon to University College Hospital, London, and professor of clinical surgery. About this time David Grant's health broke down and he went to Australia in search of sunlight, and there accepted a post as medical officer in the Lunacy Department of New South Wales. After a short visit to England he returned to Australia, and was appointed lecturer in materia medica at the University of Melbourne and honorary out-patient physician at the Melbourne Hospital. Here he made his mark, and was rapidly accepted as a sound physician, a good teacher, and a brilliant and reliable consultant. He brought with him a real culture and the inspiration of his own teachers, who included such great men as Laycock, Balfour, Fraser, Lister, and Syme of Edinburgh; and Ross, Roberts, and Thursfield of Manchester. Later, David Grant was appointed physician to St. Vincent's Hospital, Melbourne, and there, with the late Sir George Syme, he helped to lay the foundations of what has since become a great clinical teaching school. After some years of hospital work he was forced by indifferent health to retire from his honorary positions and from active teaching appointments, but he retained his unquestioned position in the first rank of Melbourne's consultants, and was respected and admired by his colleagues, junior and senior alike, so that, for a generation, David Grant's was a name to conjure with, although many of the younger men did not know him personally, so long did ill-health limit his activities and force him to abstain from public activities even within the profession. Upright, courageous, kindly, and tolerant—he was tolerant of everything but meanness and insincerity—a classical scholar, and a great lover of Scotland, whose fame he helped to spread by his own high character and good works, he is mourned by a wide circle of colleagues and patients, who trusted and admired him, and by a smaller group of intimate friends, who also loved him.

The unexpected death of Dr. WILLIAM BURNS, medical officer of the Glengall Street Dispensary and the Belfast Infirmary, caused much regret in Northern and Southern Ireland, where he was a well-known and highly esteemed member of the medical profession. Dr. Burns was a native of Belfast, where he was born sixty-one years ago. He took a very active part in medical politics, and was an outstanding figure in the recent negotiations with the Northern Government in connexion with the establishment of medical benefits. It was mainly as the result of his knowledge of the Poor Law Medical Service that a satisfactory arrangement was come to between the Northern Government and the Poor Law medical officers. He was appointed medical officer of the Belfast Poor Law Union in 1901, and dispensary medical officer for No. 6 District in 1909. During the war he was one of the medical staff of the Ulster Volunteer Force Hospital. At a meeting of the Belfast guardians many tributes were paid to his eminent qualities, and it was resolved that a vote of sympathy should be conveyed to his relatives. Among his professional colleagues Dr. Burns had many warm admirers. His candour and inoffensive bluntness when dealing with medico-political questions, of which he had an intimate knowledge, was always much appreciated.

The following well-known foreign medical men have recently died: Dr. ERNST OBERWARTH, a Berlin paediatrist, aged 59; Dr. MIGUEL GIL CESARES, professor of children's diseases at Santiago di Compostela; Dr. JEAN VICTOR AUGAGNEUR, formerly chief surgeon to the Lyons hospitals, Mayor of Lyons before 1900, Minister of Education (1914), Minister of Marine, and Governor of French Equatorial Africa, aged 76; Dr. FRANCIS X. DERCUM, a leading New York neurologist, aged 74; and Dr. HENRI GRAZIANI, president of the French Association of Mutilated Doctors.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Ministry of Health Estimates

The Estimates for the Ministry of Health, including grants in aid of benefits and expenses of national health insurance, were debated in the House of Commons on the report stage on July 29th.

NATIONAL INSURANCE: SICKNESS CLAIMS

Sir KINGSLEY WOOD said that the cost of ill-health, much of it preventable, was very heavy on the nation and on industry. In national health insurance, according to a statement authorized by the Minister of Health, there had been in recent years a rise in sickness and disablement experience so continuous and of such magnitude as to occasion grave concern. In the last year of which the House had full particulars medical benefit cost £8,700,000, of which the insurance doctors received £6,256,000, and nearly £2,000,000 was paid to insurance chemists for drugs and appliances. There was paid in sickness benefit £11,250,000, in disablement benefit £5,350,000, and in maternity benefit £1,440,000. For practically twenty years medical treatment and attendance had been available for insured persons, and £100,000,000 had been spent on it. During that time, partly as a consequence of health insurance, there had been general improvement in the public health, and medical science had progressed. Yet, notwithstanding all this and the efforts of social workers, the medical profession, nurses, and approved society administrators, there had been a marked increase in the claims of insured persons for sickness and disablement benefits, and in the consequent expenditure. This rise had been going on since 1925. In 1930 there was some improvement, but it was not considerable. Remembering the influenza epidemic of 1929 they could not draw encouragement from the figures for 1930. Societies had been affected seriously by the claim experience in respect of married women. Valuers had recently warned some societies that unless the conditions improved the whole of the present surplus would be exhausted within a few years in providing ordinary benefit. Some societies which specially catered for married women would have to cancel their additional benefit schemes altogether. The Government actuary, in his recent report to the House, concluded that the sickness claims of unmarried women had risen by 60 per cent. and the claims of married women by 106 per cent. For disablement benefit the increases were 100 per cent. in unmarried women's claims and 159 per cent. in those of married women. Among males the claims of the younger rather than of the older had increased. Figures published by one of the largest approved societies showed that the excess of claims was greater in the North than in the South of England. Sir Kingsley Wood reminded the House that Mr. Greenwood had said it could not be assumed that the great majority of the claims were due to epidemics or to unemployment. Memorandum 329, issued by the Ministry of Health, declared the increase might be due to economic or other causes not dependent on the state of health. The memorandum stated there was no collateral evidence indicating that the general health of the population was worse in 1929 than in 1921, and no apparent reason why increased ill-health should manifest itself chiefly among married women and young people. Sir Walter Kinnear, speaking a few weeks ago to the National Association of Trade Union Approved Societies at Scarborough, had said that analysis of cases submitted a year ago by a group of approved societies showed that 12 per cent. of members still in receipt of benefit were capable of work. The Secretary of the National Union of Distributive Workers Approved Society had said that national health insurance finance was being sorely tried by doubtful claims. Since the House of Commons last discussed the subject the Ministry of Health had endeavoured to strengthen the supervision of claims. He had urged approved societies to maintain effective sickness visitation, and to make early reference to the regional medical officer for examination of claims. A recent memorandum from the Minister stated that approved societies should not hesitate to refer to the regional medical officer claimants whose incapacity was certified as continuing beyond the expected period. The Minister took a new course in the same memorandum when he advised societies that

incapacity was certified as due to catarrh, chill, cold, debility, dyspepsia, or similar conditions, an immediate visit should be made by a sick visitor, and, unless that visitor's report justified delay, the case should be at once referred to the regional medical officer In a communication made by the Minister of Health to medical men, Mr Greenwood had said

"*The payment to each claimant in a year of a single week's* benefit beyond that to which he is properly entitled would have the result of speedily bringing a large proportion of all approved societies and branches into a state of insolvency"

That was a necessary reminder to the medical men The Minister of Health had made an amending regulation on change of doctors In place of the former fourteen days' notice, insured persons were now only permitted to transfer on one month's notice, at the end of March, June, September, or December Anyone associated with approved society administration during the last three years would agree that the change was necessary Sir Kingsley Wood asked if the Minister proposed further steps He was not confident that sufficient had been done to rescue the national health insurance system What was the state of the Central Fund, and how long could it sustain the claims made on it by the societies? What was the position of the third valuation of the societies?

Mr Rhys Davies said one or two small societies, according to the last valuation, had reached a stage when it would be almost impossible for them to pay the statutory benefits The Minister of Health was forcing them to join a larger society The standard of honour in relation to claims from the insured population, from the medical profession, from the dentists, and from the opticians must be improved, or else the national health insurance scheme would ultimately fail Since the war people had completely changed their attitude towards public funds There were approved societies composed of members who suffered little from bad conditions of employment low wages, or unemployment which still had an increase in the average rate of sickness claims In his own society in fifteen years there had been an increase of approximately one day per annum in the claims for benefit in respect of every male member Every attempt to reduce the average duration of sickness met with the opposite result In proportion as dental benefit was provided, there was an increase in the claims for sickness benefit The third valuation returns of trade union societies were not so bad as Sir Kingsley Wood suggested, but the segregated societies, such as those of the miners, could not carry on much longer on the present basis Approved societies which covered few but married women were obviously in financial difficulty There was something wrong in the relations between the medical profession, the Ministry of Health, and the approved societies Some members of the medical profession issued certificates which were unjustifiable The doctor had no concern with the amount of benefit paid away on his certificate

Dr Morris Jones intervened, and said the medical profession was subject to a penalty for excessive certification

Mr Rhys Davies reaffirmed his assertion, and said it was unfair that the approved societies had to pay medical inspectors to see that the 15,000 panel doctors did their work properly He made the same remark of the dental officers, and said the funds of approved societies had been unduly damaged by unjustified claims There was no way out of these difficulties till the doctors were employed by the State The International Labour Office had shown that in other countries—for instance, Austria, Brazil, and Germany—health insurance funds were affected by trade depression and by the high cost of medical and pharmaceutical benefit In Germany, as from July, 1930, every insured person had to pay 6d for his first medical certificate and 6d for his first bottle of medicine That had a steadying effect on the number of claims In Luxemburg last year there was a dispute between doctors and approved societies on the fixing and payment of medical fees British approved societies had not come to that On the whole, they and the doctors were on very friendly terms and if loose certification could be got over the funds of the societies could be again maintained He was anxious that there should be no suspicion of the approved societies checking unfairly the certificates of the medical profession but the societies were entitled to ask why 58 per cent of the persons whose cases had been referred to the regional medical officers were found capable of work

Dr Morris Jones also discussed the excess of claims for sickness benefit He could not agree that 1930 was better in this respect than the peak year of 1929, if allowance was made for the influenza epidemic in 1928 and 1929, the most serious since 1919 There was a tendency to day to try to get as much as possible for nothing and insured persons were no more guilty than any other class The next great factor was unemployment After many years of panel practice he considered that the economic depression was affecting the physical and mental health of the insured population There was no more difficult problem before the medical profession than sickness claims among insured persons, and members of the profession were as alive to their responsibilities as were the approved societies Supposing the question of debility arose That might mean anything from congenital laziness to serious ill health, but no other term would fit a real case of debility, and a medical man was bound, by conscience and honour, to certify that a person suffering from it was unfit for work Dr Morris-Jones said he knew no superstition or habit of which it was more difficult to cure the population of this country than the tradition that a bottle of medicine was a remedy for all ills He knew that the increase in sickness claims had been heavier among women Often, when a certificate had been given certifying that a woman was not fit for the insured occupation in which she was engaged, that woman was doing as arduous work in her household With regard to early notification to the regional medical officer, an inquisition would be intolerable if inspectors of approved societies were allowed to inspect certificates given by medical practitioners and to make inquiries, as it were, behind the backs of the medical men He suggested that, instead of inspectors of approved societies analysing certificates, the Ministry should state that no insurance certificate should be accepted for such a thing as a cold or a chill, but that more definite phraseology should be used He submitted that the medical men were doing their best in difficult circumstances

Mr Mellep congratulated Mr Greenwood on issuing to the approved societies and medical profession leaflets which dealt faithfully and frankly with the situation In effect, the Minister had said "Let us see whether there is something inherently wrong with the system itself or with the health of the people" He agreed with the memorandum in which Mr Greenwood had disclaimed any intention of suggesting that insurance practitioners as a whole had been responsible for the general increase in sickness claims But there was loose certification among some members of the profession Dr Morris-Jones had spoken of "debility" on a certificate That was a confession that at the moment the practitioner was unable to diagnose the disease In a few days he ought to determine the real cause of incapacity or cease giving certificates under the heading of "debility" Excellent service was given by the medical profession as a whole If it were performed by all panel practitioners the House would not complain of an excess of claims In 1922, in England and Wales, 113,000 cases were referred for examination That figure rose, till, in 1930, 531,000 cases were submitted Of the cases submitted in 1922, 40 per cent were found to be still incapable of work In 1930, out of 531,000 cases, only 34 per cent were found to be incapable of work This reflected upon the medical profession and upon the honesty of the people If married women were to be accepted for insurance three courses were open—to increase the contributions, to reduce benefits, or to enact that when a woman married she must pass out of insurance, and that if she subsequently re entered employment she must re qualify for benefit During re qualification a limited sickness and maternity benefit would be provided

Mr Thomas Lewis thought the medical profession would say that a good deal of the increase of sickness was due to the reduced stamina of the people Unless there was a marked change in economic conditions sickness experience would become worse It was curious that a layman, a sick visitor, should be asked to decide when a case should be referred to the regional medical officer He knew of patients so sent who had died the following week Sick visitors had cast upon them a responsibility that was too grave He believed the Ministry was not satisfied that the insurance medical service was what it should be The responsibility for the malingering should be put on the societies If the doctors were afraid to put people off the funds who ought to be

off, then they should be freed from the fear by a different form of service What had the doctors done for an average salary £500 in excess of what they were receiving from their ordinary practices before they took duties under the National Health Insurance Act? Sickness increased, lax certification increased, and payment to doctors increased There would be less malingering if only the doctors had the courage to do their work properly The Minister should consider that the time had come for a national medical service to include the dependants of insured persons

Mr PALMER said the medical profession could, under the terms of certification, do exactly what others were prepared to pay them to do

Miss RATHBONE suggested that one of the causes for increased sickness claims by married women was that in times of privation, as Mr Rowntree's study of poverty in York had shown, the married woman, in expending the family income, left herself to the last

Miss SUSAN LAWRENCE said she regarded with some liking the doctor who, as reported by Mr Meller, wrote "I D K" (I don't know) on a certificate It was very much the same as saying he required a second opinion Nor did she see any harm in the visitor asking for a second opinion There was nothing derogatory in that to the strictest medical etiquette All that happened was that the regional medical officer was brought in The last circular on the increase of sickness claims went out from the Ministry on May 31st, and the Ministry was conferring with the societies It was early to suggest further measures The financial position of the Central Fund was engaging the attention of the Minister, and whether it would be necessary to make a levy was being anxiously discussed The full report of the third valuation was expected in the autumn So far as it had gone, the figures were rather better than were anticipated

Sir THOMAS INSKIP said that broadly speaking the duration of sickness claims had not increased The growth in the number of sickness claims was out of proportion to the deepening of the industrial depression The Minister had called attention to the necessity of the doctors being a little more careful but the position called for something more definite and drastic He did not agree with Mr Rhys Davies's suggestion that doctors should be made to realize how much money depended on the grant of a certificate A doctor should address his mind to the condition of the patient, and not consider the consequence of granting a certificate He could not agree with the suggestion that the medical service should be nationalized, and he did not believe that any doctor sitting upon the Labour benches of the House would agree with it A great deal could be done if societies introduced a more comprehensive and organized system of sick visitation The operations of the regional medical staff should be speeded up Its usefulness to-day was diminished by tardiness If the second medical opinion could be called in earlier the right diagnosis might prevent an improper claim on a society Medical men were the kindest hearted people in the world and most members of the House if they were medical men would prefer to take the risk of passing people about whom they were not perfectly satisfied that they were ill Instead of attempting to distribute blame to the doctors or others the House should try to improve the system

Sir ERNEST GRAHAM LITTLE said that medical service under national health insurance should approximate to the conditions of private practice The latest regulations concerning the opportunities of insured persons to change their doctors was disliked by the medical profession and a unanimous resolution protesting against it had been passed at the Representative Meeting Under that regulation there was really a period of four months before the doctor could be changed, and during that period the poor man had to pay the fees of the man he had chosen which was unjust The Minister had not sufficiently considered the psychological effect of a free choice of doctor That free choice was one of the most important points in the relationship between patient and doctor and would be disastrously affected by the introduction of a State service The main objection to it came from the approved societies Sir Ernest asked the Minister to listen to the other side of the question He also drew Mr Greenwood's attention to the difference in the treatment of private and insured persons by limitation of panel prescriptions The chief cause of this limitation was the agreement made in 1927 by which the chemists on the panel had first call on the Drug Fund The arrangement had been characterized by the British Medical Association as dangerous, and he hoped Mr Greenwood would be prepared to revise it He urged the Minister not to be too severe on panel practitioners, who tried to give as good a service to panel patients as to private patients and were penalized for doing so The dissatisfaction felt by the public with the National Health Insurance Act was illustrated by the remarkable rise during the last twelve months in the attendances at voluntary hospitals Many of his own patients were dissatisfied with their treatment under panel doctors and at the hospital with which he was associated the patients included a large proportion of insured persons This experience was confirmed by figures from other hospitals His own hospital dealt with 50 000 out patients last year and a similar number was dealt with at Guy's Many of the reasons for dissatisfaction with the conditions imposed upon patients under the National Health Insurance Act could easily be removed

Dr FREMANTLE said that many of the things which had been suggested during the evening were impracticable to-day Proposals had to be limited to the capacity of the Treasury The whole House was determined to maintain the efficiency of the health services within the limits of the public purse Mrs Manning had given a good illustration of how to ensure expansion with efficiency and economy There was far too great a tendency to think that real expansion of health services must be in bricks and mortar That was an echo of various reports which the House had received It had been suggested in regard to maternal mortality, and in the case of mental hospitals and mental deficiency, a matter on which he desired an explanation from the Minister They had the same tendency in the development of local government hospitals where vast expense was to be incurred in providing greater accommodation They might have to go much more slowly in these matters Delay would not necessarily reduce efficiency Buildings were useless without the personal services to fill them, and personal services were useless unless individuals had information and understanding to use what was provided for them In this time of straitened finance the Minister would not necessarily reduce progress if he made the most use of services which existed—voluntary official or otherwise—and tried to develop maternity services nursing services home visitation of the sick, after care "pre care" and all the matters engaging the attention of associations concerned in promoting the health of the people It would be useful if the community had a short armistice from building and efforts were devoted to expanding the personal services Dr Fremantle said he could give instances where material development was being pressed at a risk to existing services What was being done to use the voluntary hospitals in the combined scheme under the Local Government Act, 1929? They must put away all prejudice and use existing hospitals He had heard of one big industrial town where there was an absolute rift between municipal and voluntary hospitals In London the voluntary hospitals were likely to be put on one side, and the municipal hospitals would suffer till they developed overlapping services In the interests of the sick poor, and in view of the exhausted purse he asked Mr Greenwood to see that officialdom was with voluntaryism, so that it would be unnecessary for him to carry out his threat to die in the last ditch before he would economize

The Minister's Reply

Mr Greenwood said Sir Thomas Inskip's suggestion on health insurance had been put into operation Sir Henry wanted more attention paid to sick visitation Half the complaints in that day's debate were that there was too much Similarly with Sir Thomas's suggestion that there should be greater use of regional medical officers Undoubtedly there were improper claims "Swinging the lead" had not been invented in the last year or two He would gladly sweep from benefit those who by making improper claims were robbing their fellows, but in tightening administration they had to be careful not to deny the just claims of sick persons Improved administration and greater co operation between all the agencies concerned were having a substantial effect In 1930 the total expenditure of all approved societies on sickness disablement benefit was £2,000,000 less than in 1929 Part of that saving was due to improved administration and

co operation between panel doctors regional medical officers, and approved societies The improvement of last year continued during the first half of 1931, and the sickness claims for the quarter which had just finished were the lowest for any quarter during several years past In the second quarter of 1931 cash values amounted to £5 250 000 against £5 500 000 last year and £5 750 000 the year before Captain Cazalet had asked about nursing homes These were administered by local authorities and the Ministry's direct contact with them was by the surveys made from time to time As regards radium practically all the funds at disposal would soon have been expended on radium and the substance allocated by the Commission In reply to another question by Captain Cazalet Mr Greenwood said the offer made to M Spahlinger by all his predecessors in the last nine years still stood They were willing to co operate with M Spahlinger or to test any vaccine or serum he might produce The difficulties were not all on one side Replying to Sir E Graham Little's remarks Mr Greenwood said the Ministry had not got rid of the free choice of doctor They had limited the rapidity with which an insured person could run from one doctor to another It might be true that the arrangement made in 1927 was not so advantageous as medical men thought it ought to be for the insured person In connexion with institutional services the Ministry had a scheme which did not satisfy everybody, but succeeded pretty well Turning to maternal mortality, Mr Greenwood said that out of 396 local authorities 216 had on July 21st replied to his memorandum which made definite suggestions for attacking the problem of maternal mortality Of these 128 had adopted proposals, and many were bringing them into operation Thirty one authorities were establishing or extending ante natal clinics 16 arranging with private practitioners for routine ante natal examination in suitable cases 17 improving arrangements for the supply of midwives 20 providing or extending hospital accommodation and 37 arranging auxiliary services He hoped members would persuade local authorities to develop this important service Times were hard but this kind of expenditure brought a substantial reward Dr Fremantle had faced the House with a conflict between voluntary hospitals and municipal hospitals Mr Greenwood thought that, taking the country as a whole that conflict was not so harsh and clear cut though in London the voluntary hospitals and their supporters were ranged on one side and the public hospitals and their supporters on the other Our existing hospital system, public and voluntary was not more than enough to satisfy our needs For a very long time the two types would go side by side Voluntary hospitals must realize that the big local authorities would desire to develop their own provision in hospitals while working in co operation with the others He hoped there would be *sufficient good will* on both sides to make the maximum use of existing hospital accommodation In conclusion Mr Greenwood said this year's Estimates showed no economy in the social services which had expanded Local authorities tramelled by hard times had steadfastly developed their essential services He was satisfied that when the money for this year had been expended the public service of this country would be more healthy and vigorous

The House then agreed to the Health Estimates as reported

Control of Opium.—Dr DRUMMOND SHIELS on July 28th informed Mr Wellock that the recommendations in the report of the Commission of Inquiry into the Control of Opium Consumption in the Far East had been considered by the Governments of the British Colonies and Dependencies concerned It was thought advisable to defer changes in the existing system of control until the Commission's recommendations had been discussed at the international conference to be held at Bangkok in November

Road Accidents in the Metropolis.—On July 28th Mr CLYNES told Mr Naylor that in the first six months of 1930 there were 648 fatal road accidents in the Metropolitan Police district In the similar period of this year since the abolition of the speed limit the number was 624

Safety in Mines.—Mr SHINWELL states that he has received from the Safety in Mines Research Board a full report on the recent series of pit trials of automatic gas detectors and is reviewing the position

A Death after Vaccination.—Mr GREENWOOD told Mr Freeman on July 30th that a medical officer of his Department had reported that the death of a child at Newport Monmouthshire after vaccination appeared to have been due to septicaemia following septic infection of a vaccinated arm Evidence of this infection appeared four days after vaccination There was no reason to consider that it had been introduced by the vaccine lymph employed The lymph used was not obtained from the Government lymph establishment, but was supplied by a well known maker The vaccination was performed in the ordinary course of practice by a medical practitioner who was not a public vaccinator

"Replanting Teeth".—Replying on July 30th, to Mr Buchanan Mr GREENWOOD said he had not considered it desirable to take advantage of an offer to give his Department the patent rights of a process of extracting disinfecting and replanting teeth The inventor's proper course was to follow the customary practice of making full scientific publication of his methods and results with a view to trial and criticism by his professional colleagues

Venereal Disease Centres.—Replying to Dr Fremantle, on July 30th Mr GREENWOOD said annual returns concerning work done on venereal diseases at the treatment centres were already furnished to his Department by the medical officers in charge of the centres He would consider whether in future, medical officers of health should be requested to deal specially with this subject in their annual reports

Telephones for Rural Nurses.—Replying on July 30th to Mr Riley Mr GREENWOOD said he had no funds at his disposal with which to give financial assistance in aid of the installation of telephones in the residences of qualified nurses and midwives in rural districts and villages but the county councils had power to make the necessary arrangements so far as midwives were concerned

A 'Remedy" for Tuberculosis.—On July 30th Mr GREENWOOD said the testimonials concerning the "umckaloabo" treatment for tuberculosis, sent to him by Mr Smithers, had been considered by his advisers and he found no reason to reconsider his view that there was not sufficient ground for instituting a clinical investigation into the value of this alleged remedy for tuberculosis

---

Medico-Legal

THE EYESIGHT TEST FOR MOTOR CAR DRIVERS

In the Court of Appeal on July 30th before the Master of the Rolls Lord Justice Lawrence, and Lord Justice Slesser, arguments were heard on an application to direct the local justices to hear and determine an appeal against the refusal of the Cumberland County Council to renew a motor driving licence The licence had been refused to the applicant Mr Edwin James Hepworth of Maryport because he had admitted his inability to answer in the affirmative the question asked 'Are you able to read at a distance of twenty five yards in good daylight with glasses (if worn) a motor car number plate containing six letters and figures?'

It was stated on behalf of Mr Hepworth that he had been driving for eight years without accident or complaint On applying for the renewal of his licence he answered "No" to the question put because the characters at that distance seemed blurred to him but he declared that he could see persons or animals on the road 200 or 300 yards away and cars at a much greater distance and that he had made long touring journeys in Scotland and England The application for a licence was refused by the authority and on the case being taken to the magistrates they held that they had no jurisdiction to hear an appeal when the refusal was based on a disability specified in the application form

Mr Charles Doughty K C who appeared for Mr Hepworth said that in the case of disabilities such as the loss of an arm or a leg the licensing authority might test the applicant's ability to drive when the applicant suffered from a prescribed disease there might be a judicial inquiry for which purpose the justices were the proper tribunal and it might be found that although suffering from the disease, the applicant was fit to drive a car The eyesight test however,

was one of the matters which did not entitle a driver to a practical test of his ability to drive when a licence had been refused on that particular ground, and if the contention of the other side was upheld he had no right of appeal as an aggrieved person

The Master of the Rolls gave judgement, in which the other Lords Justices concurred, to the effect that there was no right of appeal. Lord Hanworth said that this decision must be a matter of regret to the court, as probably it was also to the local justices. Mr. Hepworth was obviously an experienced and careful driver, and he had made a frank statement. "One cannot avoid regretting," said his lordship, "that this question should be put in the form in which it is put, because it would seem that a driver of great experience, who has shown great care and consideration for others, may be unable to answer a test made for the purpose of driving, but which may be ill-framed for the purpose of securing competence and fitness to drive." In default of the fulfilment of the test the licensing authority had no alternative but to refuse a licence. It was stated in one section of the Road Traffic Act, 1930, that a person aggrieved by the refusal of the authority might appeal to a court of summary jurisdiction, which might make an order binding upon the authority, but the court must hold that it was impossible to regard this appellant as a person aggrieved by the refusal, when the licensing authority had no alternative but to refuse. If the case was remitted to the justices, as the appellant asked, it would be their plain duty to say that they had no power to deal with it. Lord Hanworth added that it might well be a matter for those prescribing these test questions to consider whether the question regarding eyesight was framed so as to embrace cases where defective eyesight ought to be a ground for refusing a licence, and whether it did not, as it stood, cause experienced drivers to be excluded from driving when if the question was in somewhat different terms they would be able to satisfy all requirements as to capacity.

Universities and Colleges

UNIVERSITY OF LONDON

The following have been recognized as teachers of the University in the subjects indicated:

Westminster Hospital Medical School: Dr. A. J. Shinnie (Hygiene).

Lister Institute of Preventive Medicine: Dr. J. M. Gulland (Biochemistry); Dr. H. L. Schultz (Bacteriology).

Dr. S. L. Baker has resigned his appointment as Reader in Morbid Anatomy and Histology at the Middlesex Hospital Medical School as from August 31st, 1931, in view of his appointment to the Chair of Pathology in the University of Manchester.

Dr. J. A. Braxton Hicks has resigned the post as Reader in Pathology at the Westminster Hospital Medical School, in view of his appointment as Pathologist in Charge of Group Laboratories under the London County Council.

The following grants have been made out of the Thomas Smythe Hughes Medical Research Fund and the Beaverbrook Fund for 1931–32: To Dr. Richard A. Brews (Obstetric and Gynæcological Department, London Hospital), £30 for expenses in connexion with a review and follow up of all cases of hydatidiform mole and chorion carcinoma in the records of the London Hospital for the last twenty-five to thirty years, for the purpose of establishing incidence of chorion-[illegible] of proma, nature of subsequent pregnancies, renal lesions, operative mortality, prognosis, etc.; to Dr. Evelyn E. [illegible] dished (Physiology Department, London School of Medicine for protesting a) £140 for the purchase of a large sliding micro[illegible] Meeting [illegible] with Professor Lucas Keene on the development of four months [illegible] of the basal ganglia systems in the human that period the Cyril L. Oakley (University College Hospital had chosen which £30 for the purchase of animals needed in [illegible]ently considered research on the relationship between con[illegible] of doctor. That freezing and bone marrow activity; to Miss [illegible] points in the relationship of Physiology, King's College), £20 would be disastrously affected on the destruction of histamine service. The main objection experiments [illegible] has been continued as a school [illegible]ercises. Sir Ernest asked th[illegible]rs from October 1st, 1931 [illegible]side of the question. He also [illegible]p, has been appointed the [illegible]tion to the difference in the treat[illegible]t the celebrations in con[illegible]persons by limitation of panel prese[illegible] of the Royal College of [illegible] of this limitation was the agreement

Applications for the University Readership in Pathology tenable at the Westminster Hospital Medical School must be received by the Academic Registrar, University of London, by September 18th, 1931. The Reader will be director of the John Burford Carlile Pathological Laboratories at the hospital.

Applications, on prescribed forms, for the Geoffrey E. Duveen travelling studentship in oto-rhino-laryngology must be sent to the Academic Registrar by December 31st, 1931, together with a statement of the nature of the research in which the student proposes to engage, and a scheme of study submitted for the approval of the Geoffrey E. Duveen Studentship Board. The tenure of the studentship (value £450) shall be in the first instance for one year, but may be extended for one or two years.

The William Julius Mickle Fellowship, of the value of at least £200, is awarded annually to the man or woman who, being resident in London and a graduate of the University, has, in the opinion of the Senate, done most to advance medical art or science within the preceding five years and has therein shown conspicuous merit. Applications must be sent in to the Principal of the University by October 1st, 1931. Further particulars can be obtained on application to the Academic Registrar.

The following candidates have been approved at the examination indicated:

M.D.—*Branch I (Medicine)*: I. Bakhsh, P. Berry, A. [illegible] Dorothy Collishaw, G. I. Davies, R. P. P. Davies, A. Edgar, M. L. Mistri, Mary F. Pease, G. C. Pether, D. Prasad, J. H. Simmons, G. F. F. Sutton, C. E. W. Wheaton, J. A. Wood, B. A. Young. *Branch II (Pathology)*: J. N. Cummins. *Branch III (Psychological Medicine)*: F. E. L. Schneider. *Branch IV (Diseases of Women)*: Harriet E. Acheson, D. A. Blair-Bridget S. P. Gurney, Morfydd R. Jones, Joyce Morgan Jones, J. Parkes, T. V. Pearce. *Branch VI (Tropical Medicine)*: K. V. Powles, Gulbai P. Patel.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A meeting of the Royal College of Physicians of London was held on July 30th, when the President, Lord Dawson of Penn, was in the chair. The following officers were elected for the ensuing year.—*Censors*: James Collier, M.D., W. Langdon Brown, M.D., C. R. Box, M.D., Sir Charles Briscoe, Bt., M.D. *Treasurer*: Sidney P. Phillips, M.D. *Registrar*: Raymond Crawfurd, M.D. *Harveian Librarian*: Arnold Chaplin, M.D. *Assistant Registrar*: R. O. Moon, M.D.

The following Fellows were elected members of the Advisory Committee to the President: Dr. H. Morley Fletcher, Dr. Robert Hutchison, Dr. A. M. H. Gray, Dr. H. L. Eddy, Dr. H. H. Dale, Dr. J. A. Ryle, and Dr. F. Watts-Eden.

Appointments

Dr. James Collier and Dr. W. Langdon Brown were appointed to represent the College on the Mackenzie Mackinnon Trust Committee, and Sir Humphry Rolleston was re-elected representative on the executive committee of the Imperial Cancer Research Fund.

The President, Lord Dawson of Penn, will represent the College at the celebration of the 250th anniversary of the Royal College of Physicians of Edinburgh.

The President announced that he had appointed Sir George Newman to be Harveian Orator, and Dr. Dugald Baird to give the Bradshaw Lecture, both in 1932. (The forthcoming Harveian Oration in October next will be delivered by Dr. Robert Hutchison.)

In addition to the appointments to lectureships announced at the last meeting, Dr. Harriette Chick was appointed Oliver-Sharpey Lecturer, and Dr. L. P. Jacks the Lloyd Roberts Lecturer, for 1932.

Awards

The Baly Medal, awarded every alternate year to the [illegible] who shall be deemed to have most distinguished himself in the science of physiology during the two years immediately preceding the award, was awarded to Professor W. B. Cannon of Harvard University.

The President also announced the award in Edinburgh of the Murchison Scholarship jointly to W. M. Arnott and R. J. Kellar.

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members:

Wilbert Hurst Brown, M.B.Oxf., Ernest Thomas Carey, M.B.Lond., Edward Philip Nigel Creagh, M.B.N.U.I., F.R.C. Crichton Miller, M.D.Ed., Ratansha Dinsha Dalal, I.M.S. Courtenay Nisbet Evans, M.B.Lond., Joseph Hayes Fay, M.D.Ed., Mohamed Gamil Farid, M.B.Cairo, Theophil Jay Friedrich Frank, M.D.Melb., Clifford Allchin Gill, L.R.C.P.II. Howard Gillison, M.B.Ed., John Howell Halliday, M.B.S. Henry Procter Hutchinson, M.B.Camb., Harold Gordon Mc[illegible] M.B.Lond., Robert Michael Maher, M.D.Lond., John O[illegible] Mercer, M.B.New Zealand, Herbert Leslie Milles, L.R.C.P.

George Oakley, M B Camb, Rupert Samuel Bruce Pearson, M B Oxf, Evelyn Nora Popper, M D Lond, Mostyn Levi Powell, M B Melb, Gangadrum Venkataswami Ram Mohan, M B Madras, Douglas Riding, M D Liverp, William Carey Smallwood, M B Birm, Tej Raj Swarup, M B Lucknow, Abd El Kader Talkhan, M B Cairo, Alfred Brian Taylor, M B Birm, Geoffrey Fawsitt Taylor, L R C P., Thomas Fennent, M D Glasg, Hugh Ferguson Watson, M D Glasg, Charles Edward Walton Wheaton, M D Lond, Bertram Alan Young, M D Lond

Licences and Diplomas

Licences to practise physic were granted to 140 successful candidates, and Diplomas in Tropical Medicine and Hygiene and in Ophthalmic Medicine and Surgery were conferred jointly with the Royal College of Surgeons (The lists of successful candidates were published in the report of the meeting of the Royal College of Surgeons printed in our issue of August 8th, p. 280.)

The following diplomas were also conferred jointly with the Royal College of Surgeons:

Diploma in Public Health—L. W. Cann, Irene E. Chandler, Anne A. Craig, J. Crawford, M. B. Dayer, T. W. Davies, D. M. de Silva, D. Diamond, C. E. Dolman, M. J. Evans, T. I. Evans, Sarah P. M. Griffiths, C. Hill, Kathleen M. Horton, J. E. Howard, Amy L. Jagger, V. B. Kettle, Catherine B. McArthur, Hilda K. McKernan, J. Portelly, J. F. Southward, I. W. Stallybrass, R. Stuart, R. J. Toleman, Olga F. Tregelles, E. W. Vaughan, Nora W. Wamsley.

Diploma in Psychological Medicine—G. I. Bell, L. J. Bendit, A. Cannon, C. R. Cooke-Taylor, J. A. F. Denyssen, S. B. Hall, J. G. Hamilton, S. D. Isaacs, J. M. Loftus, Joyce McConnell, G. W. Murray, C. J. Thomas, L. M. Webber.

Diploma in Laryngology and Otology—G. E. Archer, M. G. J. Booysen, E. C. L. Burnier, G. V. Joglekar, B. V. P. Reddy.

CONJOINT BOARD IN IRELAND

The following candidates have been approved at the examination indicated.

Final Professional—T. J. Conlon, M. P. Crowe, P. A. Fox, J. L. Hampson, Mary G. V. McAllister, J. O'Donnell, Y. Posner, J. V. Quinn, J. Rubinstein, G. V. Steen.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following candidates have been approved at the examinations indicated:

Primary Fellowship—W. W. Bassett, J. S. Baxter, M. E. M. King, C. J. Shortall.

Final Fellowship—M. A. Parthasarathy, H. T. Fleming, D. S. Poole-Wilson.

Medical News

The Royal College of Physicians of London will be closed from August 17th till September 19th, both days inclusive.

The Fellowship of Medicine has arranged two special courses for August—namely, a course in urology now in progress at All Saints' Hospital until August 29th, and a course at the Queen's Hospital for Children from August 17th to 29th. Lunch and tea are kindly provided by the hospital authorities. Fee, £2 2s. A comprehensive course will be given at the Brompton Hospital from September 7th to 12th (fee £3 3s.); an afternoon course at the Infants Hospital from September 14th to 26th (fee £3 3s.); psychological medicine at the Bethlem Royal Hospital from September 8th to October 3rd; ophthalmology at the Central London Ophthalmic Hospital from September 15th to October 10th (fee £3 3s.). A revision course will be given at the Westminster Hospital from September 14th to 26th (fee £5 5s.), and a similar course at the Metropolitan Hospital from September 28th to October 10th (fee £3 3s.). Detailed copies of syllabus may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The Royal Sanitary Institute announces that the autumn session of training courses for examinations for sanitary inspectors, meat and food inspectors, smoke inspectors, and in sanitary science, will commence on Monday, September 28th. Syllabuses of the lectures and of the examinations, containing full particulars, are obtainable from the secretary of the Institute, 90, Buckingham Palace Road, S.W.1.

Sir Herbert Samuel has accepted the presidency of the British Institute of Philosophy, in succession to the late Lord Balfour.

At the quarterly meeting of the council of the British College of Obstetricians and Gynaecologists, held in London on July 27th, with the president in the chair, Professor J. M. Munro Kerr (Glasgow) and Dr. J. S. Fairbairn (London) were re-elected vice-presidents for the current year. A "casual" vacancy on the council, occasioned by the elevation to the Fellowship of Professor E. Farquhar Murray, was filled by the election of Mr. J. St. George Wilson (Liverpool) for the rest of the current year. Dr. T. M. Healy (Dublin) and Dr. Margaret I. Balfour (India) were admitted to the Fellowship of the College *in absentia*. It was decided that the annual dinner of the College should be held at Grosvenor House, Park Lane, London, on October 23rd. The dinner will be preceded by a ceremony for the conferment of the honorary Fellowships on the Right. Hon. Lord Riddell, Professor Paul Bar (Paris), Professor Whitridge Williams (Baltimore, U.S.A.), and Professor Essen-Möller (Lund, Switzerland), all of whom have accepted the invitation of the council, and will be followed by the conferment of the ordinary Fellowships and Memberships on those qualified to receive them.

The Minister of Health has addressed a circular (No. 1207) to local authorities advising them that the period of operation of the Housing (Rural Workers) Act, 1926, has been extended for a further five years by the Amendment Act of 1931. The new Act extends for a similar period the operation of any existing scheme made by a local authority under the original Act. Appended to the circular is a copy of a report by Sir Arthur Lowry, chief general inspector of the Ministry, of the working of the Act of 1926 in the county of Devon and in the rural district of Atcham, Shropshire, from which it appears that its provisions for the assistance of owners of cottage property could be applied to a much greater extent than they are at present. Commenting on this report, the Minister draws attention to the necessity for co-operation between the county council (where that council is the local authority) and the district councils of the county; to the economy of improving existing houses where possible compared to the erection of new ones; and to the fact that the rents paid by occupants of improved houses have not materially increased. He also reminds local authorities of the arrangements made by the Council for the Preservation of Rural England, acting in co-operation with the Royal Institute of British Architects, for the giving of expert advice, free of charge, on the execution of repairs and reconditioning under the Act.

The annual report on the health of Gibraltar for 1929 has recently appeared after considerable delay, due to the fact that the then medical officer of health, Lieut.-Colonel W. C. Smales, R.A.M.C., has taken up an appointment elsewhere. It contains an interesting survey of the various ways in which public health is safeguarded in an uncommon type of locality. A foreword by Professor Bostock Hill rightly calls attention to the excellence of the sanitation in Gibraltar, and the consequent absence of any serious infectious diseases for some years. The report is well illustrated, and contains unusually detailed information.

At the meeting of the Central Midwives Board for England and Wales on July 23rd a letter was considered from the Metropolitan Boroughs Standing Joint Committee, stating that midwives were not taking full advantage of the facilities offered for the ante-natal care of their patients, and that, though a proposal had been made that legislation on the subject should be introduced, the joint committee was not of opinion that this would be a practicable remedy, and that in any event Parliament would not be disposed to legislate specially for London in the matter. The joint committee asked the Board to use its strongest endeavour to encourage midwives to secure the proper and sufficient ante-natal examination, by medical men, of their patients. The Board, in its reply, indicated that endeavours to the ends suggested in the letter were being made, and that it would be glad of any suggestions which might be of assistance in the matter. Approval as lecturer was granted to Dr. James Campbell Gordon, Salisbury General Infirmary.

kidney for the removal of a large stone; this patient similarly made a good recovery without further symptoms. In the third case a double left kidney was found, the upper half of which was converted into a pyonephrotic sac. This was drained for three months, and at a second operation the kidney was resected, the upper half being separated from the lower half at the level of a sulcus dividing them. The recovery of the patient was prompt and complete. The author suggests that resection of the kidney is neither extremely difficult nor risky, and in properly selected cases is a very advantageous operation.

135 Chronic Pancreatitis

J. Hertz (*Bull. et Mém. Soc. Nat. de Chir.*, May 23rd, 1931, p. 689) reports three cases of chronic pancreatitis which were treated surgically. In the first case symptoms of pain, vomiting, and nausea had been evident for eight years, and an exploratory laparotomy revealed a tumour the size of a mandarin orange at the head of the pancreas, which was united to the duodenum by adhesions. The second case was similar, pain and sickness having been present for five or six years; a pancreatic tumour as big as a thumb was found. In each of these cases the abdomen was closed without anything further being done, but the symptoms were immediately relieved. When seen several years after operation the patients were in good health, had gained in weight, and had had no recurrence of pain or sickness. In the third case the symptoms, which were acute, had been troublesome for five years. An *x*-ray examination revealed a hypertonic stomach, with some deformity in the first part of the duodenum. Laparotomy showed that the head of the pancreas was enlarged, whitened, hard, and stony. Since there were calculi in the appendix, appendicectomy was performed, followed by free incisions into the gland. A gauze drain was then placed in these incisions, and the wound was closed. A pancreatic fistula developed on the fifth day, but dried up quickly, and the patient made a good recovery. The interesting feature in these cases was the disappearance of pain and improvement in the condition of the patients following an exploratory laparotomy.

136 Treatment of Burns

Robertson and Boyd have claimed that the toxaemia of burns is due to a toxin, which circulates in the blood, is adsorbed by the erythrocytes, causes the symptoms seen in cases of severe superficial burns, and may bring about death. F. P. Underhill and R. Kapsinow (*Journ. Lab. and Clin. Med.*, May, 1931, p. 823), who report a series of investigations, are unable to corroborate this statement. They believe that the symptoms obtained experimentally by other workers are explained by the inclusion of significant quantities of alcohol in the extracts of the skin. Injections of normal blood produce practically the same symptoms and effects in guinea-pigs as those of the blood of burned animals. The present authors suggest that the symptoms and effects of a burn may be adequately explained by the establishment of a degree of blood concentration due to loss of fluid from the damaged area. There is no need, therefore, to postulate the existence of a "burn toxin." Treatment of burns resolves itself into the prevention or alleviation of shock, the maintenance of the blood concentration at a level compatible with life, and local treatment of the wound so as to avert infection and facilitate healing. With such safeguarding the authors are satisfied that a greater measure of success will attend the treatment of burns.

137 Sympathectomy and the Coronary Innervation

D. Danielopolu, L. Marcou, and G.-G. Proca (*C. R. Soc. de Biologie*, June 3rd, 1931, p. 419) agree that the coronary arteries have a sympathetic and parasympathetic innervation. They describe experiments which prove that the sympathetic fibres are vaso-dilators and cross the stellate ganglion, while the parasympathetic are vaso-constrictors and reach the vessels through the vagus. These findings confirm those of Anrep and other investigators. Section of the vagi increases the coronary output; excision of the stellate ganglion reduces it considerably. The parasympathetic fibres arise from the bulb, as do the inhibitory filaments of the heart; supply to the coronary arteries, with that to the myocardium, has its origin in the upper dorsal cord, which, by its sympathetic filaments, increases the work of the heart and also the coronary output. The bulb inhibits this organ and reduces its circulation. This circulation is maintained by the amphotropic coronary tonus, which may be modified by reflexes acting on these vessels. If the reflex predominates on the vaso-constrictors, the vaso-dilators are excited and vaso-constriction is moderated. If the vaso-dilator group is intercepted, the reflex travels only by the vaso-constrictors, and vaso-constriction becomes more intense. The authors discuss (ibid., p. 421) these facts in relation to the stellectomy of Leriche, and describe how they affect their own operation in the treatment of angina pectoris. The section of the coronary vaso-dilators in these operations can cause an intense spasm of the vessels, and lead to cardiac arrest. This partly explains the cases of sudden death after stellectomy.

Therapeutics

138 Indications for Digitalis

According to R. Wybauw (*Le Scalpel*, May 6th, 1931, p. 592) the chief indication for digitalis is failure of the myocardium; in cases of dilatation with pulmonary oedema and right-sided dilatation, strophanthus or ouabain occasionally gives better results. Although a compensated myocarditis does not always call for the exhibition of digitalis, it may be tried sometimes to prevent failure of compensation. As a rule hypertrophied hearts react better to digitalis than those with no enlargement. Sinus arrhythmia is not improved by digitalis, nor is paroxysmal tachycardia, which may be arrested by injections of ouabain. In bradycardia, digitalis is contraindicated; extrasystoles are not as a rule benefited. In complete heart-block, when there are signs of failing ventricle, digitalis may be tried. In auricular flutter, digitalis may convert the flutter into fibrillation, which is less painful, and is attended by the best results. In advanced cases it is advisable to prepare the way for digitalis by inducing diuresis, by free action of the bowels, and by ouabain injections. The pathological conditions in angina vary so much in different cases that no general law can be laid down; the state of the myocardium determines whether digitalis is likely to do any good. In pseudo-angina of neurotic origin it is inefficacious. Among the general contraindications to digitalis therapy the author mentions digestive disturbances, idiosyncrasy, and a tendency to embolism.

139 Inhalation Therapy in Angina Pectoris and Intermittent Claudication

Y. Henderson (*Amer. Heart Journ.*, April, 1931, p. 548) remarks upon the increasing use of carbon dioxide for therapeutic and prophylactic purposes. Not only has this gas the power of stimulating the respiratory centre, but it also exerts a marked effect upon the circulation. This fact is shown in animal experiments in which it is found that a sufficient amount of carbon dioxide must be present in blood for perfusion in order to preserve adequate diastolic relaxation of the heart. It seems likely that the Nauheim treatment, which consists in carbonated baths, owes its value more to the inhalation of carbon dioxide than to the effect of the gas upon the skin. Henderson has administered carbon dioxide to three patients suffering from angina pectoris. A stream of the gas was passed into a mask which was sufficiently open to allow free respiration. Mechanical precautions were taken to prevent accidental excessive administration, and after continuing for two or three minutes an almost maximal depth of respiration was developed. The stage of increased rate of breathing was never reached. The inhalations usually lasted for fifteen minutes. The treatment resulted in improvement of the colour and temperature of the skin

A fuller circulation became apparent, and after some weeks of daily treatment it was found that pain on effort occurred less readily. Two patients suffering from intermittent claudication were also treated by daily inhalations of carbon dioxide. In both there was a marked improvement in the circulation of the ischaemic limb, and in one of them a distinct cumulative beneficial effect was observed.

140 Treatment of Prostatitis

E. SPELKENS (*Bruxelles-Médical*, April 19th, 1931, p. 739) states that at the beginning of prostatitis local treatment must be suspended; rest in bed, attention to the bowels, warm enemata, urinary antiseptics, warm baths, rectal diathermy, and suppositories of ichthyol and belladonna with papaverine chloride are all useful in the early stages. When the acute stage is ended, massage of the prostate on alternate days and the instillation of protargol or argyrol into the posterior urethra are advisable; vaccine treatment often gives good results, especially if a combination of various vaccines is used. To combat the general weakness tonics may be given, such as arsenic, quinine, and glycero-phosphates. Milk injections are more useful in acute than in chronic prostatitis. Any tendency to constipation must be dealt with at once.

Disease in Childhood

141 Cholesterol, Oedema, and Nephritis in Children

. K. CALVIN and A. H. GOLDBERG (*Amer. Journ. Dis. Child.*, May, 1931, p. 1066) conclude from a review of the literature and their own experimental observations that he blood cholesterol level in the nephrotic syndrome is practically always considerably above normal. It has a endency to rise and fall with the increase and decrease of oedema; exceptions are not uncommon. The appearance and disappearance of the oedema precedes the changes n the cholesterol. The cholesterol may be synthesized rom the deposits of fat in the body; in the nephrotic syndrome it has difficulty in passing from the blood to he tissues, since the ascitic fluid has a very low cholesterol content. The blood cholesterol in the nephrotic syndrome an readily pass through the kidneys into the urine, though he hypercholesterinaemia antedates by a considerable period the lipoiduria (Murphy). The diet has no influence on hypercholesterinaemia, but the output of cholesterol in the bile is diminished in the nephrotic syndrome, so that there is apparently a real retention in the blood (Herrnstadt). A symptomless but definite hypoglycaemia exists in nephrotic children (Knauer). It seems probable, then, that hypercholesterinaemia results from the disturbance of fat metabolism accompanying the nephrotic syndrome, and is not the cause or consequence of the oedema.

142 Juvenile Tuberculosis in Massachusetts

D. ZACKS (*New England Journ. of Med.*, May 14th, 1931, p. 1037) reports the results of a special investigation into the health of school children between the ages of 5 and 15, which was begun in 1924. It is assumed, as a working hypothesis, that tuberculosis is contracted in childhood, and that those who survive the initial infection later develop the adult type of disease as the result of a sufficiently massive reinfection. The age group 5 to 15 shows the lowest mortality figures, and it was hoped that investigation of that group might yield some clue to the mode of development of the adult type of disease. More than half of the school children came under observation; 30 per cent. were found to react to tuberculin skin tests. The reactors were subjected to an *x*-ray examination, physical examination being reserved for those showing definitely pathological *x*-ray appearances. Both childhood and adult types of tuberculosis were reported to the board of health, and immediate sanatorium treatment was recommended in all cases of pulmonary disease. In the year 1929–1930, 49,000 children were examined in the clinic, and 5,000 in the yearly follow-up. Two white children in every hundred showed *x*-ray evidence of the childhood type of tuberculosis; in many cases the coexistence of cervical adenitis pointed to milk infection; these childhood lesions, formerly often considered unimportant, have frequently been observed during the follow-up period, to be succeeded by serious apical disease. The weight being persistently below the average, or failure to gain weight, is stated to be a more important symptom than actual loss; in both girls and boys the average age for the commencement of apical lesions is 13.5 years. Of every thousand school children examined, one was found with the adult type of disease, 2.8 girls being affected for each boy. More than half these cases were diagnosed by *x*-ray examinations and skin tests only, though physical signs developed later; more than half showed *x*-ray evidence of childhood lesions, often calcified. A family history of tuberculosis was obtained in two out of every three cases of apical lesions—a most significant point. Zacks adds that though this investigation has yielded no positively new information, it emphasizes the value of the systematic examination of school children, and especially of performing a preliminary *x*-ray examination of reactors to the tuberculin test.

143 Diagnosis of Tuberculosis in Children

V. POULSEN (*Amer. Journ. Dis. Child.*, April, 1931, p. 783), who reports five illustrative cases in patients aged from 5 months to 5 years, remarks that while the diagnosis of pulmonary tuberculosis is not very difficult when distinct infiltrative processes can be detected by the stethoscope or *x*-ray examination of the lungs of a child with a positive tuberculin reaction, in cases in which such examination is negative the diagnosis is impossible unless tubercle bacilli can be found in the expectoration. Since children as a rule swallow their expectoration, the search for tubercle bacilli is not likely to be successful unless they are looked for in the material obtained by gastric lavage by direct microscopy, cultivation on Petroff's medium, or inoculation of guinea-pigs. Pouisen's cases show that children may have pulmonary tuberculosis even with an open process in the lung without there being a focus discoverable by auscultation, or anything definite being found in the skiagram. In such cases the revelation of tubercle bacilli by gastric lavage establishes the diagnosis, and renders treatment possible at an early stage. Since gastric lavage, however, is both unpleasant and costly, it is unnecessary to use it in obvious cases of pulmonary tuberculosis or tuberculous meningitis, but it is applicable in all other cases, including tuberculosis of the joints, bones, or kidneys, which is most frequently secondary to disease of the lung. Gastric lavage is most valuable in children with positive tuberculin reactions and vague symptoms, in whom it is desirable to discover whether the tuberculous process is in the lungs or in the mediastinal lymphatic glands. Of 110 children aged from 1 to 8 years, 53 showed tubercle bacilli as the result of gastric lavage. The bacilli were more easily found in young children than in older ones, as is shown by the fact that of 62 children under 3 years old 41 were bacillus carriers, whereas of 48 over the age of 3 only 12 were carriers. It is important to realize that a single examination of the material obtained by gastric lavage is not sufficient. Of the 53 cases tubercle bacilli were found at the first examination in 38, at the second in 12, at the third in 2, and at the fourth in one. The examination, therefore, should be repeated at least twice, and in suspected cases three or four times.

144 N. R. CHRISTOFFERSEN and J. A. FREDERIKSEN (*Ugeskrift f. Laeger*, May 28th, 1931, p. 587) have checked Pirquet tests in children with bacteriological examinations of the contents of the stomach, washed out in the fasting state with 200 c.cm. of water. Among 36 Pirquet-negative children, 10 of whom were under 1 year old, 10 over the age of 5, there was not one in whose stomach tubercle bacilli could be found. But among the 12 Pirquet-positive children there were 4 in the contents of whose stomachs tubercle bacilli were found.

Obstetrics and Gynaecology

145 Endometrial Hyperplasia

According to C. F. Fluhmann (*Surg., Gynecol. and Obstet.*, June, 1931, p. 1051), hyperplasia is a characteristic pathological process affecting the endometrium, and should be considered as part of a definite clinical entity. In the gynaecological department of the Stanford University school of medicine it was present in 12.2 per cent. of 507 women with abnormal uterine haemorrhage. The majority of cases occur just before and during the menopause; approximately 75 per cent. of these patients were multiparae, and in about 30 per cent. a pelvic morbid condition was also present. The outstanding symptom is uterine haemorrhage, which may be either profuse at the menstrual intervals, or prolonged; continuous or intermittent. The endometrium shows marked hyperplasia of both glands and stroma. Epithelial proliferation is occasionally noted and may give rise to erroneous suspicion of carcinomatous changes; coexistence with carcinoma has been described, however, and must be borne in mind. The ovaries show cystic ripening and atretic follicles, lutein cysts, and an absence of mature corpora lutea. An excessive production of oestrin during the course of this disease has been demonstrated; evidence is advanced suggesting that hyperplasia endometrii is the direct result of an over-stimulation of the endometrium by oestrin, and the complete absence of progestin influence. The chief local factor causing the haemorrhage is tissue necrosis, due either to a sudden cessation of oestrin production or to a prolonged, excessive oestrin stimulation. The disease is evidently the result of an endocrine disorder rather than a local pelvic condition; the anterior part of the pituitary gland may possibly be involved. Repeated curetting in younger patients, and intrauterine radium applications in those of the menopausal age are said to be the most satisfactory methods of treatment.

146 D. J. Cannon (*Irish Journ. Med. Sci.*, June, 1931, p. 279) records a case of irregular uterine haemorrhage. Operation revealed a considerable increase in the stroma of this organ, without multiplication of the epithelial elements of the mucosa; a follicular haematoma of the ovary was also present. Cannon remarks that in such a condition curetting always indicates an endometrium of normal thickness, and scrapings are usually thrown away as of no significance; even their examination by a pathologist may result in a report that the endometrium is normal because no glandular changes are to be seen. The association of a follicular haematoma with metropathia haemorrhagica is of assistance in homologizing this condition with the nymphomania of the rabbit and ferret in the absence of copulation. In both the human condition and the nymphomania a fibro-cystic state of the ovaries is found, and also evidence of a prolonged follicular phase or pro-oestrual development. The author discusses briefly the mechanism of bleeding in cases of metropathia haemorrhagica, and suggests that the cause may be removal of the hormonic influence of the ovary. In his case there was cystic degeneration, with haemorrhage into the cyst wall, which affords additional support to this hypothesis.

147 Endocrinology of the Climacteric

J. S. Diasio (*Med. Journ. and Record*, May 6th, 1931, p. 444) quotes references from the literature in support of his contention that the climacteric is a glandular dysfunction involving the ovary and one or more of the ductless glands. After trying various combinations of desiccated endocrine extracts, the best results were obtained by the oral administration of a pluriglandular mixture containing thyroid, 1/10 grain; whole pituitary, 1/20 grain; suprarenal, 1/10 grain; and gonads, 3/4 grain. In the majority of cases relief followed in three days, but the treatment had to be continued for a considerable time to ensure permanent benefit. Such oral treatment gave, he found, very satisfactory results when carefully supervised, and in order to ensure this the author encourages the patient to come at least once a month for an intramuscular injection of the same formula. Though many of the climacteric symptoms are not necessarily ovarian, they point to a compensatory action of the functionally related endocrines, dysfunction of the ovary causing a similar manifestation in one or more of the other glands.

Pathology

148 Posture and the Circulating Blood Volume

Working on the discovery of Thompson and his associates (using the dye method) that posture affected the total plasma and cell volumes, R. L. Waterfield (*Journ. of Physiol.*, June 6th, 1931, p. 110) found that the blood volume, determined by the carbon monoxide method, is less in the erect than in the recumbent position. This loss, mainly in respect of plasma, averages 15 per cent. of the total plasma volume; an accompanying loss of 4 per cent. of the total cell volume also occurs. The increased plasma-protein concentration present in the erect posture is such as would be expected if the globulin fraction alone did not diffuse through the capillary walls. The findings of observers using the dye method differ somewhat from Waterfield's; the differences are enumerated, and are explained by a diffusion of the dye into the lymph spaces. The blood volume does not include the splenic blood. The spleen may contract and throw its red cells into the circulation in certain subjects. The increase in plasma volume following splenic contraction is probably derived secondarily from the tissue fluids. With reference to Thompson's suggestion that the loss of plasma is due to leakage into the tissues of the lower limbs, Waterfield found (ibid., p. 121) that the volume changes in the leg corresponding to changes in posture are such as would occur from the blood volume changes, and are apparently due to an actual oedema of the tissues. They are greatest in subjects that are tall, in poor training, and have fat, flabby legs.

149 Complement Fixation with Besredka's Antigen

A. Bessemans and J. Morelle (*C. R. Soc. de Biologie*, May 1st, 1931, p. 1298) state that it has been previously shown that the fixation of alexine by Besredka's antigen is of great value in the diagnosis of ocular tuberculosis. They report the results of this test in 557 other cases: 215 of proved or suspected tuberculosis; 129 non-tuberculous controls; 125 cutaneous cases of little-known origin, such as alopecia or psoriasis; and 88 allergic cases (bronchial asthma or prurigo). From the results the following facts are deduced. Since an advanced state of the lesions, the presence of complications, and the patient's poor general state decrease the percentage of positive reactions, the test is of some prognostic value. Allergic affections, notably asthma and prurigo, give a high percentage of positives. Psoriasis, alopecia, and erythematous lupus also yield a high percentage of positives; this may indicate a tuberculous etiology in these diseases. Cure or amelioration of Besredka-positive affections can cause a diminution or disappearance parallel to the positivity; therefore, repeated tests should be made to aid in prognosis. No parallelism exists between the tuberculin skin reaction and that of Besredka, but there is a certain inverse relation between the incidence and frequency of positives with the age. The diagnostic value of this test is very limited in non-pulmonary tuberculosis, but is much greater in commencing and suspected pulmonary cases, and in certain affections of doubtful origin.

150 Influenzal Bacteriaemia

E. L. Benjamin (*Arch. of Pediat.*, May, 1931, p. 3[illegible]) records the case of a male infant, aged 8 months, who was taken suddenly ill with cough, vomiting, fever, and signs of pneumonia in the left lung. *B. influenzae* was found on blood culture and in a serous fluid from the left chest. Symptoms of meningitis developed nine days after the onset, and death followed. *B. influenzae* was also found in the purulent cerebro-spinal fluid. There is no record of a necropsy.

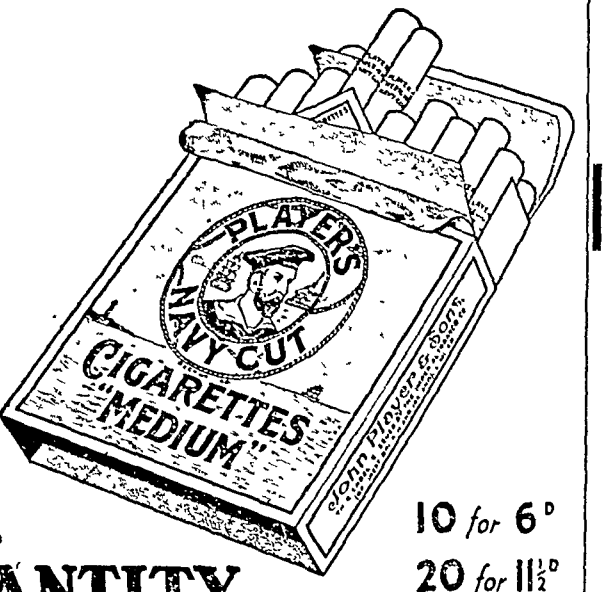
DURING PREGNANCY

IN the preparation for motherhood  be the patient a young primigravida  or an experienced multigravida  slim and delicate  or generously built  besides the routine tests  among your urgent instructions  will be

"Regular bowel movements daily." That will prevent many a headache, feeling of lassitude, and perhaps hæmorrhoids in the later months. You can prescribe AGAROL safely, because it exerts no effect upon the uterus nor does it interfere with lactation. Besides it is easily taken because it is palatable without artificial flavouring.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

A supply gladly sent for trial.



AGAROL BRAND COMPOUND *for Constipation*

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopiable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

"ARDENTE" STETHOSCOPE.
Mr R H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B M A Meeting

MEDICAL REPORTS
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk, also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee joint
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in. × 15in. × 11in.

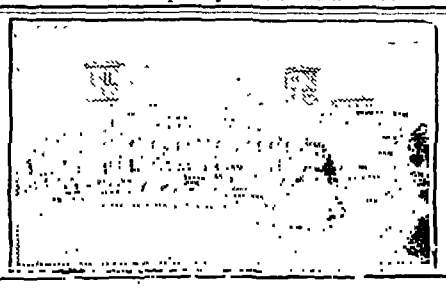
BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).



President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMPACT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. BERRY, M.R.C.S., L.R.C.P., Torr House, Chagford, Devonshire. Telephone 11 CHAGFORD. Telegrams "TORR, CHAGFORD."

NEURALGIA AND NEURITIS

Few diseases cause so much suffering as nerve pains, such as sciatica, trigeminal neuralgia, brachialgia, and intercostal neuralgia.

This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that of 100 patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved.

Pistany RADIO-ACTIVE Mud Packs and Compresses are simply and easily applied. This treatment may be successfully combined with other physiotherapeutic methods.

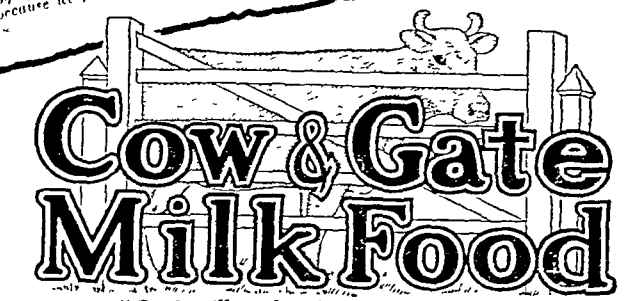
BABY'S ONLY FOOD FROM BIRTH TO 2½ YEARS

ROSARIO
16th May, 1931

To Messrs. Cow & Gate, Ltd.
Guildford, ENGLAND

Dear Sirs,

Until two months ago Baby has been existing only on Cow & Gate milk, as she refused to take any solid food. Everyone told me she ought to be eating other food, but evidently what she did have made up for it, and everyone remarked how bonny she was and what strong bones and muscles she had. We would not be without it for worlds and thoroughly recommend it to all our friends.



She still has three breakfast-cups a day—one on getting up in the morning, one at siesta time and one on going to bed—and thoroughly enjoys it and has never had one minute's discomfort, even during our extremely hot summer days. She is very intelligent and bright.

I remain, Yours very truly Hilda J. Taylor.

We make no apology for publishing this mother's letter in the Professional Press—because we feel that it will be of clinical interest.

"Eucortone"

(Cortical Extract of Suprarenal)

In the treatment of

Addison's Disease

Efficacy established by biological tests and clinical use

(*Journal of Physiology*, June 6, 1931: *Proc. Physiol. Soc.* May 2, pp. 4, 5, and 9)

"Eucortone" is prepared by the method of Swingle and Pfiffner, and is highly successful in the treatment of Addison's Disease. Particularly striking is the rapid restoration of appetite, weight, strength, and feeling of well-being. Biological tests and clinical use show that "Eucortone" contains the long-sought cortical hormone in an active state and is free from adrenalin activity. The extract contains no irritant or toxic substance, and is sterile.

1 c.cm. is equivalent to 30 grams of cortex. In rubber capped bottles of 25 c.cm.

Further particulars on application.

Allen & Hanburys Ltd., London, E.2.

Telephone: 3201 Bishopsgate (ten lines) Telegrams: "Greenburys Beth London"

"I-so-gel" Granules

Indicated in Chronic Constipation, Colitis, and allied intestinal disorders

"I-so-gel" is a natural vegetable material. The granules absorb many times their volume of water and swell into a gelatinous mass which both stimulates natural intestinal movements and soothes inflamed intestinal mucous membrane. Indicated in chronic constipation, colitis, and allied intestinal disorders. Action purely mechanical. Sugar-free. Ideal for diabetics.

In bottles at 2/6 and 4/6 each

Descriptive literature sent post free on application.

ELASTOPLAST BANDAGES

are not only the proved cure for Varicose Ulcer, but are also ideal for all Surgical and Orthopaedic work, for Varicose Veins, Sprains, Strains, Dislocations, after treatment of fractures, etc.

Elastoplast is the only elastic plaster bandage with the correct degree of elasticity to ensure perfect compression and support.

ELASTOPLAST DRESSINGS

combine medicated gauze and lint pads with the elastic base, providing speedy and efficient dressings for Cuts, Wounds, Incisions, Boils, etc.

VARICOSE ULCER

Vide British Medical Journal, August 8th, 1931, pp. 266/7. Paper read in the Section of Dermatology, British Medical Association.

"The treatment employed by the speaker consisted essentially in supporting the leg by means of a bandage of elastic sticking plaster . . . The bandage was changed only at considerable periods. The speaker had cured 525 cases of ulcer of a total area of 25 square feet."

A later speaker:—"As regards dermatitis, he had never seen a case which had not yielded to a second and tighter application of Elastoplast."

Ulcer of 1½ years' duration.

VISCOPASTE BANDAGES (Unna Paste Type).
A valuable adjunct to the after-treatment of Varicose Ulcer.

Elastoplast

Patent No. 253,527.

BRITISH MADE.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P.O. value 2 6 (Overseas postage extra) by the manufacturers:

T. J. SMITH & NEPHEW, Ltd.

HULL. LONDON. GLASGOW. MANCHESTER.

Enquiries to Dept. B: 42, Tavistock Sq., London, W.C.1

OBTAINABLE THROUGH ALL SURGICAL SUPPLY HOUSES

After 13 weeks' treatment with Elastoplast.

It must be understood that the acceptance by the British Medical Association of an Advertisement does not imply a recommendation, and that no responsibility is accepted with regard to the accuracy of the statements therein contained.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

Educational Number

*

*

September 5th

THIS Special Number of the British Medical Journal will contain full information, brought completely up to date, for the guidance of those about to enter the Medical Profession and of Graduates wishing to secure the higher qualifications. Particulars of the Public Health Service and of the medical work in the Forces are also given.

Statutory requirements and the necessary formalities associated with Medical Practice are reviewed, making this issue a reliable and useful work of reference which may be relied upon to provide an answer to those questions which most frequently arise in connexion with Medical Education and Registration.

A careful study of the advertisement pages of this Special Number will be amply repaid. Publishers have made a special effort in compiling lists of books bearing on every phase of medical training; also, numerous announcements set forth in detail the facilities offered at the various Colleges and Medical Schools, including matters of special interest to Post-Graduates. Many firms specializing in the professional and private needs of the doctor have arranged to insert interesting announcements on this occasion.

It should be noted that the Educational Number replaces our ordinary issue for September 5th, 1931, and will be forwarded to Members of the British Medical Association in the customary way. The cost to those not already enjoying the privileges of Membership will be 1s. 3d. per copy.

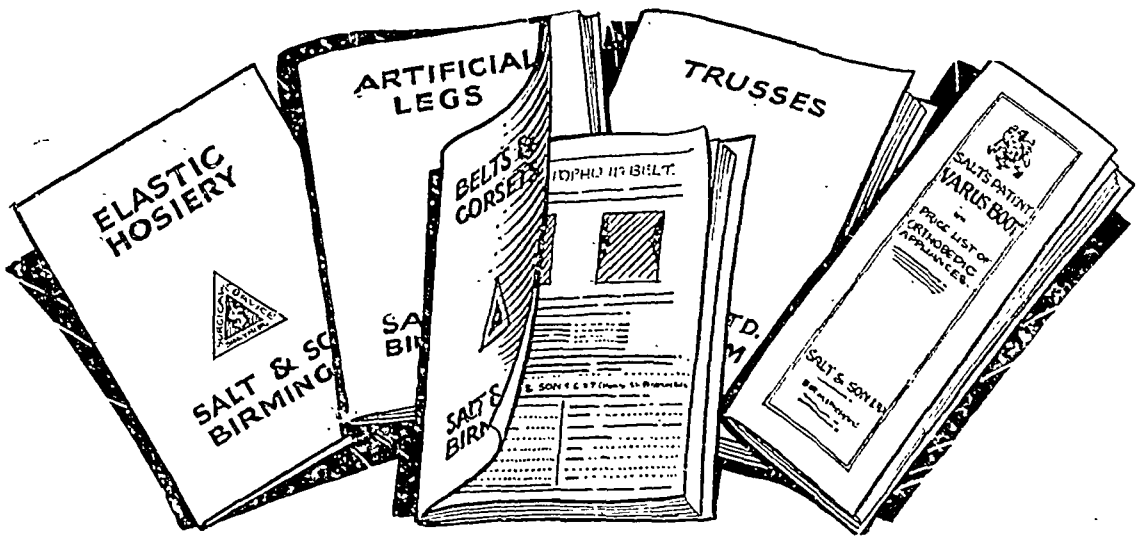
WHERE APERIENTS FAIL SURGICAL BELTS SUCCEED!

The introduction of X-ray photography has swept away many previously held conceptions of the pathology of the abdomen. This new method of examination has shown unmistakably that therapeutic measures such as the use of aperients and intestinal antiseptics are futile in the presence of mechanical displacements. It has revealed that the safe, scientific and effective measure in innumerable cases is to correct the mechanical fault in the engineering system of the abdomen by suitable upward support. Such support is given in specific complaints by Domen Surgical Belts.

Domen Surgical Belts provide ample support upwards from the pelvis. They counteract the downward pull of gravitation—the underlying cause of mankind's tendency to sag. And Domen Belts achieve this upward support without cramping or binding the patient. Domen Belts are light, and durable, and strong. On receipt of your card or a telephone request, full particulars will be forwarded.

DOMEN SURGICAL BELTS
DOMEN BELT CO. LTD., 26, SLOANE STREET, LONDON, S.W.1. Telephone: Sloane 3524.

"Kodak" X-Ray Reduction Camera



A simple and solidly built camera. Reduces negatives of any size up to 17 x 14 ins.

Suitable for making bromide prints or transparencies of $6\frac{1}{2}$ x $4\frac{3}{4}$ size or smaller, and lantern slides.

An automatic focussing scale makes the "Kodak" Reduction Camera exceedingly simple to operate.

Evans'

PURGOIDS

Purgoids present a most effective combination of Phenolphthalein, Aloin, Ipecacuanha, Belladonna, etc., in sugar-coated tablet form. They are of great value in cases of constipation, peristalsis being promoted without griping, and intestinal secretion increased.

In addition to their use in constipation of long standing, Purgoids are to be commended as a general aperient in temporary conditions and after operations.

Cool & Comfortable in Hot Weather

AND THE MOST EFFICIENT SUPPORT ON THE MARKET!

The Curtis Abdominal Support Model No. 1 Skeleton type is lighter and more hygienic than any other support on the market, whilst its efficiency is in no way impaired. The average weight for a person with a hip circumference of 32" is only 10 ozs. All covering is detachable and washable, and each appliance is supplied with a spare set of covers at an inclusive charge of £3 : 12 : 0.

The Ideal Laxative

REGULOL REGD.

IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

"Regulol" is available in two forms: "PLAIN" or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

SAMPLE 1-lb. JAR FREE ON REQUEST.

Please indicate whether Plain or Compound is required.

(This offer is limited to the British Isles.)

CUXSON, GERRARD & CO. LTD., OLDBURY. BIRMINGHAM.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Local Anæsthesia in Surgical Practice

CANCER OF BREAST.

Typical Case.

D. H., female, aged 50 years.

Diagnosis: Carcinoma of the right breast.

Operation: Radical excision of the breast.

Anaesthesia: Brachial block, intercostal block, midline infiltration; 240 c.c. of 0.7 of 1 per cent. of Novocain-adrenaline solution.

Operation: Preliminary blocking, the first to the seventh thoracic nerves being blocked. 10 c.c of the solution were used in the region of each nerve. Brachial anaesthesia, midline infiltration. A Wolff graft was used to close the skin defect. In this case the anaesthesia was excellent, although the amount of solution used was comparatively small.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (FAIT).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

WHAT CAN'T BE CURED MUST BE ENDURED

Surely such passive suffering is no longer necessary, as *prevention* is the key-note of all medical thought in regard to *incurable* diseases. Many diseases of the teeth cannot be cured, but the means for their prevention are known to, and practised by, professional men.

Cure is the voice of the past—*Prevention* the divine whisper of the present.

And it is in this vital matter of prevention that Gibbs Dentifrice is allied to the work of the Dentist. The formula for Gibbs Dentifrice is one that is heartily endorsed by leading Medical Authority; because it provides just those qualities demanded.

Gibbs Dentifrice has a saponaceous base and mild alkaline reaction. It produces a fragrant antiseptic foam that penetrates to every interstice and crevice of the teeth and mouth — removing all decay-causing deposits. The polishing agent is of just the correct texture to clean and polish without risk of abrasion. Moreover, Gibbs Dentifrice is very pleasant and economical in use. By giving powerful publicity to Gibbs Dentifrice in the National Press, Gibbs help the Doctor and Dentist to extend the scope of preventive dentistry.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The product has been approved by important members of the Medical Profession.

Gibbs Dentifrice

OVALTINE

IN GALACTOSIS

Diet in lactation is a matter of no less importance than diet during pregnancy.

"Ovaltine" completely meets the requirements of the diet of the nursing mother by providing adequate and appropriate nourishment.

It is easily digested, wholly nourishing, and does not convey any noxious or unpalatable substances to the breast milk. For these reasons "Ovaltine" will be found a most dependable prescription for establishing galactosis.

"Ovaltine" is recommended to be given about the sixth month of gestation and should be continued throughout the nursing period. A rich milk secretion is thus encouraged and the health of the patient safeguarded against overstrain.

As an example of the nutritive power of "Ovaltine" it may be stated that one cupful yields more nourishment than 3 eggs or twelve cups of beef-tea.

A liberal supply for clinical trial sent free on request.

EXAMPLE OF THE ILLUMINATOR'S ART IN THE TIME OF CHARLEMAGNE AND HIS SUCCESSORS. INITIAL LETTER OF THE ANGLO-CAROLINGIAN SCHOOL.—The superb initial letters for which the Carolingian manuscripts are remarkable, are instinct with historical associations. The delicate, intricate patterns with birds' heads take us back to Ireland and the work of the Keltic monks in the sixth and seventh centuries, and then to the Anglo-Keltic school of Northumbria, one of the world's chief centres for the production of MSS. in the seventh century. Interwoven with these features are forms of animals of eastern origin apparently derived from the designs upon ecclesiastical garments of rich silks. These designs were already incorporated into the ornament employed in the MSS. in Britain when Alcuin of York, passing into the service of Charlemagne, introduced it into the Frankish empire, where they were combined into fresh forms. In addition, Græco-Roman foliage based upon the acanthus then began to be employed and gave it a characteristic Carolingian touch. The illuminated initial here reproduced is taken from a manuscript which represents the highest achievement of the Teutonic period in art.

Observations
ON
TREATMENT OF CHILDREN AT THE SEASIDE (EXCLUDING SURGICAL TUBERCULOSIS) *
BY
CARL HABERLIN, M.D.
WYK AUF FÖHR

It is to me a special favour to be allowed to speak about thallassotherapy in the country where physicians, far in advance of other nations, not only recommended but also first practised it to a great extent. It was Russel who, in 1750, invented "the sea," and Lettsom in 1791 founded the first sea hospital at Margate. In Germany, Lichtenberg (Gottingen) proposed with success in 1792 to introduce sea-bathing. Beneke (Marburg) made in 1850 the earliest scientific researches, basing himself partly on Margate, and established in 1881 the first of his sea hospitals in Germany. Beneke intended to have the first establishment at Norderney. On request of the Crown Princess (later Empress Frederic) he founded, in September, 1881, the very first hospital at Wyk, on the island of Föhr. The Crown Princess thought its climate singularly like that of the Isle of Wight when she stayed here on a visit with her children.

Marine climates in spite of many common qualities, are far from uniform and have great differences. In England these differences are well recognized, much more so than in France. Fox and others discussed them before the Royal Society of Medicine in 1928. As general characters, the bracing east, the sedative west, and a mixture in the south might express the main qualities in England, though individual and seasonal differences are important. The German Ocean coast resembles generally the English south east coast, my observations refer mostly to the German North Sea. It is important to recognize that the English climate is on the whole far more equable and less Continental than that of Germany.

RESPIRATORY CATARRHS

The greater number of sick children coming to the seaside suffer from respiratory catarrhs, chronic or continually relapsing, in the nose, throat, trachea, or bronchi. We have found in the island of Föhr that the treatment of these catarrhs is very satisfactory, as regards both immediate and permanent results. Moll (Vienna), with a large material, records 80 per cent. permanent cures at the sea as against 60 per cent. in mountain climates. Our statistics show 80 to 90 per cent. permanent cures at the seaside. Certainly it is on account of good results that crowds of such invalids have recourse everywhere to the seaside, coming often without medical advice, merely by reason of their knowledge of similar cases. To this category belong especially children who during the cold season fall from one cold into another, they are not only oversensitive to colds but also oversusceptible to infections. They constantly miss school, have often to be kept in bed, and suffer a long time from high temperatures after acute illness. Their parents become perplexed and nervous, and finally complete a vicious circle by unsuitable pampering. In most cases the fever soon ceases by the sea, but the secretion decreases only after a while, until it gradually disappears. The susceptibility to colds becomes less, and even should a cold in the head be caught it does not lead as a rule to a feverish bronchitis. It is somewhat longer, however, before the susceptibility to infections falls to a normal point.

Special attention must be given to the throat. Most of our small patients from large towns suffer from more or less chronic pharyngitis, no wonder, since the unwholesome and polluted air continually passes over the mucous membrane of the nose and pharyngeal cavity, where the dust and bacteria are mainly deposited. These conditions are favourably influenced by sea air, though it often takes a very long time. Smaller adenoid growths usually decrease so far as no longer to hinder the breathing. Corresole and Jaubert found a spray with sea water very beneficial. Larger growths ought to be removed before beginning the cure. Chronic relapsing inflammations of the tonsils, for which other forms of treatment have proved ineffectual, have in many cases so much improved that acute attacks become very infrequent (Engel, Fisch). Many operations, especially on children under 6 years, are thus avoided.

To the affections of the respiratory organs we may add asthma. Constitutional predisposition and, above all, neuropathic factors here take a part. Practical experience shows us very good results by the sea, in most cases the little invalids have no attacks at the seaside, if, however, their stay is too short, they often have relapses. A complete cure requires from half to one and even two years, winter by the sea being more important than summer. Summarising statistical data we find permanent cures in from 30 per cent. to 70 per cent. of these cases (Nicolas, Haberlin, Gmelin, Roeloffs). But such words must be used with caution, as even after a great number of years relapses are possible. The favourable results obtained are due to a variety of causes: (1) cessation of the harmful and excessive irritation of the mucosa (dust, germs, smells, and, in winter, the hot, dry air of houses),† (2) cessation at the seaside of irritation of the skin, which may be just as harmful (clothing, staying indoors, overheating), (3) restoration of full movement in the mechanism of breathing (*after life in enclosed living rooms, at school and at home*). An air more or less free from dust and germs and without breath hindering smells is inhaled instead, without overheating in winter and dryness *of the air in rooms*. *In the abundance of open air*, even the clothed body is surrounded and stirred by the almost continuous sea breeze. With lighter clothing air baths bring new stimulation to the skin (cool temperatures, wind, radiation), and even in winter gymnastics and games give plenty of exercise. By such measures the most important function of the skin, the regulation of warmth, is exercised with most satisfactory results.

In examining the reaction to an application of ice to the skin of children newly arrived from large towns we see a long latent stage and a faint appearance of reactive redness. After some weeks at the seaside the reaction is considerably quicker and stronger. Thus in a series of experiments with 70 children in 67 per cent. the latent time was shortened and the reactive redness became stronger. If the rectal and skin temperatures of newcomers are examined after a cold bath the following types will be found: 1. The rectal temperature sinks considerably, rises slowly again, yet not to its former height (50 per cent. of the examined). 2. The rectal temperature sinks only very little immediately after the bath, later a little more, rises slowly again, but not to its former height (20 per cent.). 3. The rectal temperature rises immediately after the cold bath, sinks again, and reaches finally the last point (20 per cent.). 4. The changes are very small (±0.3°) in 9 per cent. of the children. Of these four forms you must

* Vide in opening a discussion in the Section of Hydrology and Climatology at the Annual Meeting of the British Medical Association, Swansea, 1931.

† Leonard Hill: In schools where during the period of heating good ventilation through opening of windows was not carried out, the number of lessons missed on account of colds was on the average six times larger than in schools which had a good ventilation.

consider number 1 as bad, number 3 as good. The 50 per cent. bad ones are diminished at the seaside to 28 per cent., the 20 per cent. good ones are increased to 32 per cent. (N.B. At the last examination the temperature of the air and water was considerably less.) In a second series of investigations surprisingly similar numbers were found, the good reactions becoming much more frequent, from 21 to 46 per cent. The measuring of the temperature of the skin shows, of course, a sinking after the cold bath (from 1-5° on the back to 8-9° at the feet). At the end of the stay at the seaside, skin temperatures on the whole, but especially in cool weather, were less, the lowering after the cold bath considerably more, rising promptly again, but never as before to a point at or above the initial temperature. It may be noted that mechanical irritation of the skin by means of the capillar-reactometer (Nothaas) showed that the latent time for the appearance of red dermographism became in 65 per cent. of cases shorter.

Chest expansion increases from 2 to 3 cm., the frequency of breathing lessens, and the vital capacity increases from about 300 to 500 c.cm. (Häberlin). An increase of inspiration measurement was shown in more than 1,000 children; the expansion rising from 4.9 to 7.2 cm., which signifies not only better ventilation, but better circulation in the lungs (Hézer and Spehl: "Plus le poumon contient de l'air plus il contient de sang"), and therefore better conditions of nourishment for the whole organ. The skin is no longer flabby and pale, but tense, its circulation being much more active. Intracutaneous injection of tuberculin shows that the reaction begins, rises and falls again more quickly. We may infer from this an increase of immunity. Dr. Percy Lewis has made the same observation; he says, "at seaside schools the chief effect noticed is improved resistance to infectious diseases." The fact that the diffuse radio-shadows of the hilus gradually show a sharper outline (although only after six to twelve months) points to the same conclusion.

Diseases of the organs of respiration are subject to locally harmful influences which are exogenous and also in no small degree to endogenous influences. There are certain constitutional changes which are favourable to catarrhs and exudations. Such pre-disposed children incline especially to bronchial and tracheal catarrhs, often relapsing and of long duration. Climatic influences are of importance to counteract the endogenous as well as the exogenous factors of etiology. A "lymphatic" tendency plays a part in the lymphatic pharyngeal ring (chronic relapsing tonsillitis and adenoid growths), in relapsing rhinitis and pharyngitis. A marine climate is one of the best cures for this condition.

Nutrition

If we treated first the organs of respiration it was because far the greater part of our patients come on account of these to the seaside. The fundamental and most characteristic effect of a sea cure is not its influence on particular parts, but on the whole body. The "Umstimmung" (toning or tuning up of the whole body), a polyvalent allergization, an omnicellular strength increase, is not a method of treatment of sick organs through direct influence on the seat of the disease, but an alteration or modification of the whole body. The healthy tissues, enhanced in their capabilities, render to the diseased part the resources which threatened to fail. We often have little patients who do not thrive in their homes, but an evident reason for this standstill of development is not to be traced. They are simply at a stop in the development of weight, breadth, haemapoietic function, and strength; they remain without energy and appetite. In such cases we see almost without exception satisfactory and often astonishing results. King Brown remarks that in cities the cooling power of the body is very low; this keeps the "level of metabolism of the inhabitants below that of country dwellers, and this in its turn means a general lowering of vitality." It is not only the outer form which is favourably changed, but also the inner consistence. Especially the N-retention is improved (Löwy, Müller, Schadow); and assimilation of phosphorus, sulphur, calcium is favourably influenced (Robin and B. Binet; F. Müller and E. Müller).

Heat production amounted to 2,700 calories per diem on a North Sea island, while the same children in a large town only had 1,445 calories, and in a forest convalescent home near a large town only 1,500 calories (Häberlin and F. Müller, 116 children). The consumption of oxygen is also increased in a sea climate if the patient really stays by the sea—that is, on the beach, and not in his room or a restaurant. There are considerable differences in the amount of the increase. Delicate and weak children show a far higher increase than others.

Observations were made on the beach with and without clothing, and unclothed at the sunbath, and in warm and cold sea baths. As to the increase of oxygen in the sunbath it is important that under the same circumstances in Hamburg increase was absent, surely in consequence of the fact that under the almost continual motion of the air on the beach all overheating and with it the appearance of the reflex chemical increase of warmth was avoided. This action of the air and sunbath has been well characterized by Fox in the words "coincident application of heat and cold." The thyroid gland appears to be exceedingly susceptible to climatic conditions (Cf. highland and lowland thyroid glands). The greater content of iodine in the air and in foods from flooded districts of the sea coasts has doubtless an influence on this organ. Hallowes (Torquay) reports "children with deficient thyroid glands are much benefited." I have the same experience as other German physicians. But the iodine alone cannot be the only cause. Bergfeld found a deficiency of ultra-violet rays responsible for the origin of goitre, and the content of calcium in drinking water is of importance (Gigou). We may in general concede that the endocrine glands participate in influencing the body at the seaside; the time of the menses, for instance, is often delayed. Under various external influences (light, thermal, and mechanical stimulus) histamine-like products appear to be formed in the skin which may be very active (Harris, Lewis, Ellinger). Intra-organic oxidation may also be influenced by radiation, baths and injections of protein (Gerharts, E. Meyer and Reinhold, Freund and Gottlieb).

Metabolic changes have been observed particularly during rest, for instance at the sunbath. It is well understood that an increase of metabolic change which takes place without work is of special importance. There is no greater combustion in the muscles, since neither motion takes place nor is muscular tonus increased. We first think of an increase of combustion in the liver. Such an increase without simultaneous increase of work might lead to regeneration of cells, and that would signify modification and rejuvenation of the body (Kestner). Under these baths the muscular strength increases—the maximal power as well as the whole working power, as measured by Collin's dynamometer and Weiler's Arbeits Schreiber (Cazin, Haberlin, Berliner). It is a characteristic feature that this also takes place with patients who are kept in bed (*training in repose*, as the French have it).

Gastro-intestinal System

Very often we have children whose appetite is exceedingly small and whose digestion is very slow. The want of appetite disappears promptly in 95 per cent. of the cases. If the patients are not with their parents or nurses, but are taken to a well-managed children's nursing home,

it is all the better. However salutary the psychical influence may be, one cannot ascribe the whole effect to this. We saw above that the calories rose from 1,450 at home to 2,700 at the sea. Also the increased movement of the children cannot be the only cause, from the investigation already quoted on children in a convalescent home near a town. The sea climate, therefore, seems to play a special part. We might probably find the reason in the higher demand which the wind makes upon heat production. The continual stimulation and refreshing of the skin involves an increase of metabolism; a great deal of combustible matter is used, and the increased combustion prevents the heat regulation from failing. Surely the inverse balance between the distribution of blood in the splanchnic and in the peripheral areas (skin) plays a part (Dastre-Morat; E. F. Müller). By this mechanism the circulation of the intestinal organs is raised, and also their activity of secretion. Chronic constipation disappears generally after the first day, notwithstanding that in many cases it is severe, and may be atonic or spastic. We generally remark that the circumference of the abdomen gets smaller, from increased tonus of the intestines and abdominal muscles, and rectal prolapse disappears. Organic diseases of the digestive organs are not here considered; we have good results with functional, motor, secretory, and resorptive insufficiency. Nervous dyspepsia is mostly cured.

Children with neuropathic pains in the abdomen often come to us; these little vagotonic patients usually are cured; the removal from unsuitable surroundings has to be taken into account. In exudative cases we often meet with mucous colitis, which is favourably influenced. The connexion of the thyroid gland with the bowel has also to be considered.

CARDIO-VASCULAR SYSTEM

Cases of uncompensated morbus cordis are always refused; with compensated cases we see (but only in summer) some benefit. The proper domain of the sea climate is functional disease of nervous and overworked persons. In these we always see excellent improvement or permanent cure, as in the invigoration of the heart of convalescents. The cardiac muscle becomes stronger *without* tiring work. But the influence of the sea climate upon the peripheral circulation is more important. For this special indication the sea climate seems to me to stand first among all physical remedies. The changes effected in the skin have been already noted. The play of the vasomotors becomes more active, the peripheral circulation increased. It may be added here that the blood pressure falls after air baths for some time and rises after cold baths for a short time, with slower pulse. After a cure of six weeks the acceleration of the pulse remains the same immediately after exertion, but goes back sooner to normal. With hearts in any way affected, the acceleration after exercise becomes greater and the return to normal slower. The number of erythrocytes and also the percentage of haemoglobin rise considerably at the seaside. Some good observers report a favourable influence on pernicious anaemia, as also on leukaemia.

RHEUMATISM

Between rheumatism and the catarrhs there are some analogies; and formerly articular rheumatism was known as *catarrhus articulorum*. Endogenous and exogenous conditions co-operate. A type of constitution, sometimes described as asthenic, hypoplastic and exudative, seems to predispose to rheumatism. Infections proceed mostly from the throat and tonsils. Cold and chilling clearly play a very great part, either by mobilizing latent infections or preparing the ground for new ones. Rheumatism shows a seasonal curve similar to catarrhs. The pathological importance of insufficient circulation of the skin described by Fox and others should be especially considered. It is certain that such a deficiency can be essentially improved under the influence of a sea climate. We have already seen that diseases of the throat and tonsils are favourably influenced, and the increase of immunity conditioned, by climatic causes. If Garrod considers chronic articular rheumatism as an insufficient reaction to infection, we might state that stronger reactions to different irritations are regularly observed after treatment at the sea. The view that in all cases of rheumatism heat alone is beneficial can no longer be held. The best prophylaxis is a hardening treatment, and our experience in rheumatism is confirmatory, though not so distinctly as with catarrhs.

NERVOUS DISORDERS

It is very rare for a child to be sent to us merely on account of nervousness, but the number of those in whom nervous symptoms accompany constitutional weakness or definite physical disorders is legion. The children are restless, fidgety, easily frightened, changing in mood and appearance, quarrelsome, with uncontrolled affections; they have headaches and twitchings, wet their beds, lack concentration, and are easily tired—in short, the usual symptoms of neurasthenia of grown-up people. We are exceedingly satisfied with the results of treatment of these conditions. Where unfavourable results were observed it was generally after treatment not carried out carefully enough. A child with irritable nervous weakness can be over-excited by the abundance of new impressions at the seaside. Above all, the wind and the immediate neighbourhood of the sea, with its manifold stimuli (however pleasant) for the eye and ear may act unfavourably. Repeatedly we observe that such children get out of hand, or, as the mothers say, become very naughty. Removal from the actual beach, with more rest and lying down, almost always put things right at once. It is obvious that great individual differences are present which cannot be foreseen even in the most careful examination. Children with whom the sea does not agree are exceedingly rare. Psychological investigations have shown that, in general, motor excitability rises and mental attention slackens. Work at arithmetic is much quicker; work of precision better. The effect of residence in a stronger wind was shown to be great diminution of attention and increase of irritability.

With all the above-named troubles we find, as a rule, an extraordinary improvement; night terror disappears, the facial phenomenon diminishes (Falk). Naturally it is not possible to make a hereditary nervous constitution perfectly healthy, but a reduction in the degree of irritability is usually obtained, the work at school improves in quality, and over a long time. I wish to state expressly that we are far from ascribing these effects to the climate alone. The educational element and the removal from the usual surroundings are important. But, weighing our words most carefully, we are convinced that cures at the seaside cannot be replaced by anything else of equal worth.

CHILDREN FROM THE TROPICS

As to the applicability of the sea climate to children from the Tropics I have naturally a very small practical experience. The few cases coming to us show mostly a general state of weakness with special localization in the digestive and respiratory organs. They represent pretty much the state of convalescents after more or less exhausting illness. I was not able to note any difference from the favourable results which follow in similar cases from Europe. To hear something about this from the treasure of English experiences will surely enrich my knowledge of sea climate

Technique of Treatment

As regards the technique of the treatment, it may be stated that since the sea climate imposes a certain strain upon the body, it must be carefully applied. The individual reaction cannot be known beforehand. With delicate persons it is well to prescribe at first lying down; with nervous children the stay on the beach itself must be limited. With many other forms of sickness, on the contrary, a benefit is only to be obtained through remaining close to the sea, especially with susceptible respiratory organs and retarded development. Care of the skin forms an essential part of our whole treatment. The often astonishingly relaxed skin is rendered tonic and active by dry rubbing, simple washing with cold sea water, air and sun baths, warm sea baths followed by cold shower baths, or by cold sea baths. Here is the place to state expressly that the sea climate is not to be played with. We see each year the most incredible follies and extravagances in the treatment of children at the seaside, amounting almost to brutalities of parents towards their children. Such are the prolonged and repeated sea and sun baths, endless wading in the water or unlimited stay on the beach and in the wind. In all our remedial measures very brief, often repeated, stimulations are the most effective, while prolonged cold baths, for instance, have the contrary effect and defeat the hardening process, which is our objective. With school work also one must be careful at the seaside. It is not surprising to me that an English observer, Dr. Marvel, said "he doubted whether sea baths did not produce more harm than good." Russel cautioned, too, against dangerous exaggerations:

Marina aqua . . . . magna vi pollet; sed imperiti facile ipsa perperam uti possunt.

Even Homer knew this action of the sea to be very exacting:

ὀυ μεν εγωγε τι φημι κακωτερον ἀλλο θαλασσης ὑνδρα γε συγχευαι

Gymnastics are an important part of our cures. As in the colder season air baths are only possible with quicker motion, games are indispensable.

One has to be very careful about the diet of delicate children at the seaside. Suitable food powerfully assists in the process of healing, and in children prone to exudations dietetic measures are indispensable. In winter we use a quartz lamp, vitamin preparations, and sometimes arsenic and iodine, and often local treatment for adenoids. At marine hospitals with large numbers of children infections may play a large part, which has led a German paediatrician to use the same words as did Dr. Marvel on account of the danger of overdosing. Quarantine of all newcomers should be considered, and perhaps active immunization—for instance, against diphtheria. Both these measures are practised in France.

It is obvious that a short period of treatment will not suffice for chronic or constitutional diseases such as those which are mostly sent to us. We have to allow four weeks for acclimatization, which represents a certain allergical stage. Then only the benefit of our climate begins to develop fully. In general a period of less than three months' duration would not have the desired and lasting result. In more serious cases of catarrhs, asthma, debility, imperfect development, from half to one year, or even more, is necessary. To interrupt this period by a change of climate is generally inadvisable so long at least as we see a child deriving benefit. There are naturally some patients with whom one has an impression from the beginning that the sea climate does not agree. These will be sent as soon as possible to another climatic resort. It should be especially noted that for most respiratory catarrhs, and for asthma, treatment is more important in winter than in summer, and should correspond with the winter climax of these affections.*

The increase of weight in the children at Wyk auf Föhr is at its maximum in autumn. We have also noticed that the more serious retardation of development, which in summer shows little progress, is all at once improved in the autumn.

On the whole the sea represents such a powerful source of invigoration obtainable for a great part of mankind that we can fully agree with the saying of Russel almost 200 years ago:

rem de qua agimus nec levem esse, sed dignam principis cura tutelae utpote quae ad universam populi valetudinam pertinendam spectat.

PRURITUS ANI†

BY

W. P. MACARTHUR, M.D., F.R.C.P.I.

BREVET-COLONEL, R.A.M.C.; CONSULTING PHYSICIAN TO THE BRITISH ARMY

I have been asked to discuss the variety of pruritus ani of adults caused by *Enterobius vermicularis*, a nematode now removed from the genus *Oxyuris* for the reason that its characters do not conform to those of the genotype, *Oxyuris equi*. To some this contribution will seem uncalled for, but so long as one can encounter persons who for years have endured the nightly torments of enterobius without the true cause of the pruritus being discovered, or its nature even suspected, an apology for dealing with so commonplace a subject is unnecessary.

The ingested ova of *Enterobius* hatch in the duodenum. The larvae at first inhabit the small intestine, and later migrate to the caecum, where the majority of the worms exist. The appendix is a favoured habitat. About two weeks are required to complete the cycle from ovum to ovum. In 5 instances of infection in which I obtained strong evidence indicating the source, the symptoms in 4 commenced on the 15th day, and in 1, on the 14th, after the apparent exposure. The gravid females make their way to the rectum and anus to oviposit, and if not repelled by the cold they may be seen thus engaged just inside the anal canal. It is their wriggling movements which cause the irritation loosely called pruritus; it is not an itching, however, but a very quick, light, tickling sensation, most intolerable to the victim. Worms may be found outside the intestinal canal in the neighbourhood of the anus, on clothing, etc., but I do not know if this complete emergence is voluntary, or if the parasites have been displaced in scratching. They have considerable powers of resistance to expulsion by natural means, for an ordinary evacuation may leave an active pruritus quite unaffected. Possibly they escape this danger by retiring into the rectum, as they can be observed to do when exposed to cold.

As there is no multiplication of parasites within the body the number infecting the host is determined by the number of ova swallowed. Auto-infection by the mouth is the rule, and appears to be specially provided for by nature. An infestation which persists for more than about six weeks is almost certainly kept up in this way. Although the host reinfects himself with the utmost readiness, it is curious that members of his family in daily contact with him for years usually escape contamination.

* A seasonal physiological periodicity of certain respiratory functions is known. The alveolar CO_2 tension is in winter 42 %, summer 36 (Lindhard, Straub); the frequency of breathing is higher in winter and the depth of breathing less. That these could not be obtained in England (Haldane, Priestley and Lorrain) seems due to the island character of the British climate, which does not show the same meteorological contrasts as the climate of continental countries.

† Read in opening a discussion in the Section of Dermatology at the Annual Meeting of the British Medical Association, Edinburgh, 1931.

Enterobius sets up a catarrh of the intestine, and the accompanying increased secretion of mucus may be very obvious. The mucous membrane of the lower part of the rectum is congested and usually shows small haemorrhagic spots, a condition which probably extends throughout the intestine, as similar changes have been repeatedly found in the appendix. Some degree of eosinophilia is the rule, and this suggests that the general and nervous symptoms may not entirely be due to sleeplessness and mental distress.

Symptoms

Pruritus, so called, is the most constant symptom. It may commence very suddenly, and the subject of an infestation of long standing may remember the exact moment when it was first felt. If only a very few parasites are concerned their individual movements may be distinguished one from the other, but with large numbers the sensation is continuous. Even one worm may make itself felt. In two of my cases there was a distinct recurrence of pruritus after treatment had been completed; in each the capture of a single *Enterobius* gave immediate relief without other treatment.

The pruritus is mainly nocturnal, commencing shortly after the patient goes to bed, and quickly reaching its maximum intensity. Especially in cold weather the patient may get to sleep only to be wakened later. A hot water bottle in winter hastens the onset. In severe infestations he may be driven almost demented by the irritation, losing all control of himself, and tearing at the affected part until he draws blood. Some discover for themselves that vigorous movements of a finger inserted into the anal canal may give relief, due, as we know, to destruction of some of the worms. The itching ceases sometime before morning, and is never felt say, about 5 or 6 o'clock, nor before rising. I should consider an absence of this morning remission strong evidence against enterobiasis. Some itching may be felt more or less intermittently during the forenoon and afternoon, especially after exercise. In the evening, irritation is more likely to be troublesome, and is intensified by a warm atmosphere, and by the proximity of a fire, the patient often notices a sudden relief when he commences to undress in a cold room. But the daily irritation, if present, is always slight in comparison with that felt at night. One of my patients used to speak of going to bed as "descending into hell."

The discomfort and loss of sleep thus caused lead to mental irritability and despondency, which are aggravated by the fact that the sufferer often conceals his infirmity through some feeling of delicacy, and so his family do not make allowance for what they regard as mere bad temper. In the end he reaches a pitiable state of depression, and may become tearful when describing the miseries he endures.

Various reflex phenomena may develop, such as gastric hyperacidity, indigestion—probably due in part to intestinal catarrh—and frequency of micturition. The significance of these symptoms may not be appreciated. One patient complained to me of frequency of micturition of a few weeks' duration. Various examinations and tests were carried out before it was discovered that he had suffered from nocturnal pruritus—which proved to be due to threadworms—for over a year. Another case is still more instructive.

> The gentleman in question had been afflicted with pruritus for over ten years. Symptoms of gastric hyperacidity and indigestion had persisted more or less throughout this period. These were first attributed to duodenal ulcer and an appropriate course of treatment was prescribed but without lasting relief. Next chronic appendicitis was diagnosed and the supposed offender removed but with a similar absence of benefit. Presumably the appendix contained no threadworms. Later, owing to the quantity of mucus passed by entery was suggested, and emetine administered, followed by a course of stovarsol, but the symptoms were unaffected. Throughout this period many forms of local treatment, including *x* rays, had been given for the pruritus, which persisted notwithstanding. Ten years after the onset, enterobiasis was suggested for the first time, a diagnostic rectal wash out showed the presence of many threadworms, and a course of salt and water injections ended the irritation and the whole train of secondary troubles.

The excessive production of intestinal mucus, already mentioned, may result in the involuntary passage of the secretion, especially when the patient takes exercise or drives a car. It may be troublesome enough to necessitate the wearing of a pad of cotton wool.

Enterobiasis occasionally causes attacks of appendicular colic leading to removal of the appendix, which when examined is found to contain worms. This experience has suggested appendicectomy as a curative measure in persistent infestations, a wholly unjustifiable procedure, for persons who have previously undergone this operation for any reason are just as liable to infestation as others, and are no easier to cure. The activities of the parasites within the appendix and the resulting damage to the mucous membrane, may lead to the development of acute appendicitis.

Owing to *laceration and abrasions of the anal region*, an eczematous condition may be set up, which quickly disappears when the parasites are removed. On the other hand, there may be surprisingly little local injury after years of nightly scratching.

The old nursery symptom of nasal itching may be in evidence. Possibly this is a provision of nature for insuring that the infected hands are brought into the neighbourhood of the mouth. The wife of one patient who eventually proved to have enterobiasis told the medical attendant, months before the condition was diagnosed, that she thought her husband must be suffering from "worms" because he was "always scratching his nose"!

Diagnosis

In every case of nocturnal pruritus ani, enterobiasis should be considered as a possible cause, and the suspicion either confirmed or negatived by further examination. The most thorough diagnostic measure is a rectal wash out *which must be administered when pruritus is active*. If a satisfactory search cannot be carried out because of the presence of faecal matter, the rectum should be cleared by an ordinary soap and water enema given in the evening, before pruritus commences. The patient then goes to bed, and a wash out with normal saline is given later when pruritus becomes troublesome. Three or four ounces of saline is all that is required, and after a few minutes this is returned into a suitable receptacle, and examined for worms. This examination must be made carefully, and if living worms are not seen, suspicious-looking objects should be removed and examined under the low power of a microscope, or with a hand lens. It is surprising how easily shreds of mucus, vegetable matter, etc., may be mistaken for *Enterobius* if not removed and examined.

Microscopical examination of the faeces for ova is of little help. Occasionally ova may be found, but their absence signifies nothing. A positive result is much more likely if scrapings from the neighbourhood of the anus or some rectal mucus, are examined.

A very useful preliminary test is for the patient to give himself a wash out with strong salt and water (see under Treatment) when the pruritus is at its height. If this ceases instantly and does not return until the following night, the diagnosis of enterobiasis is practically certain.

It is surprising how seldom, in adults, worms are seen in the faeces. One patient of mine, a medical man, looked at every motion passed during a period of several weeks. Although nocturnal pruritus was constantly present, only a single worm was seen, and this in a motion resulting from a sharp purge given as part of his treatment.

Treatment

Prolonged infestation always results from auto-infection by the mouth, and until this source of supply has been cut off no treatment can be effective. The ova are deposited in enormous numbers in and around the anal region. They may reach the mouth either directly by the hands or they may be smeared over the body and clothing, and the hands reinfected later from these sources. Crushing of worms either in scratching or otherwise liberates eggs in large numbers. I have recovered several dozen eggs from a single finger-nail, and Professor D. B. Blacklock tells me that he has found ova in washings made from garments as low down as the knee. From this it is obvious that the washing of the hands before food and after defaecation, as often directed, is totally inadequate. The hands must be washed thoroughly every time that the surface of the body, or an undergarment, is touched, for there is no certainty that eggs have not been picked up. For example, on waking, the hands must be washed before the morning cigarette and cup of tea. Suppose the patient next rises and removes a vest, then another washing is necessary before he shaves, or cleans his teeth. In dressing, further contamination is likely, therefore the hands must be washed again before breakfast, and so on throughout the day. Laxness in this respect will be followed by vexatious reinfections. Even with scrupulous care, occasional disappointments will be experienced. Nature is unceasing in the attempt to complete the life-cycle of the parasites, and if auto-infection is prevented the infestation will die out of itself.

Treatment proper falls under two heads: first, the removal by lavage of the adult female worms which have migrated to the rectum, and second, attempts to destroy the developing stages in the caecum, appendix, and neighbouring parts of the intestine. For the first-mentioned purpose nothing is superior to salt and water in a strength of 2 tablespoonfuls to the pint. If this should cause griping, reduce the salt by half, and increase later if possible. Four ounces of the solution is sufficient for an injection, which can be given most readily by means of an infant's 2-oz. enema bulb, the patient remaining recumbent, with the hips raised, during the operation. Probably he will be unable to retain the solution for more than one or two minutes, and when it is ejected the itching is found to have ceased completely, and is not felt again during the night. It is essential that the patient should administer this treatment for himself, because it is useless if given at any time that pruritus is not felt. A preliminary simple enema, more elaborate apparatus, and larger quantities of fluid, are unnecessary complications. When a sufferer who has been wakened nightly for months or years finds that a simple procedure completed within a very few minutes will protect him from the tortures of pruritus, at once his whole outlook on life is altered.

The second part of treatment is the administration of anthelminthic drugs in the hope of destroying the parasites before they migrate to the lower portions of the large intestine. It is difficult to assess their respective values, for most of the preparations recommended are either given with some laxative or themselves act as purgatives, and a sharp action of bowels due to any cause may give a temporary relief from pruritus; for this reason sufferers from undiagnosed enterobiasis sometimes attribute their troubles to constipation. I do not know of any drug so efficacious as to do away with the necessity for rectal irrigations. Indeed, it is difficult to see how anthelminthics can reach worms lurking in the appendix and caecal pouches, and so long as even two or three are left they may suffice to drive the host into a state of frenzy. On the whole, my experience has been that when a patient finds that a rectal injection gives instant relief from his sufferings, he prefers not to be inconvenienced by purgative drugs, even though his course of treatment might be shortened thereby. Of the preparations usually recommended, I have found 2 grains of santonin combined with ½ a grain of calomel distinctly helpful. Stovarsol had no appreciable effect. Carbon tetrachloride is reported to be very efficacious, but its employment is hardly justifiable in simple enterobiasis which can be cured with certainty in other ways. Oil of chenopodium and butolan I have not tried.

Treatment, especially lavage, may affect the remarkable periodicity of *Enterobius*, the commonest change being an earlier descent of the egg-laying females, so that pruritus may be troublesome before bed-time. But whenever it may appear, a rectal irrigation with salt and water will stop it at once. Rectal irrigations, given as advocated, do away altogether with the necessity for application of mercurial ointments and the like.

I do not know to what extent pruritus ani is met with in general practice, nor can I say what proportion of these cases is due to enterobiasis. My submission is that enterobiasis should be considered as a possible cause in every case of pruritus ani in adults.

TREATMENT OF GENERAL PARALYSIS OF THE INSANE BY INDUCED MALARIA

NOTE ON FIFTY CASES

BY

ROBERT LEES, M.B., Ch.B., M.R.C.P.Ed.

EDINBURGH

Since the introduction on a large scale of malarial treatment of general paralysis of the insane by Wagner von Jauregg in 1917, great interest has been aroused in the subject, and this therapeutic measure has been extensively practised by numerous workers. The literature is already considerable; it has been fully summarized by G. de M. Rudolf,[1] by Surgeon Rear-Admiral Meagher[2] and by J. Gerstmann.[3]

This communication is intended as a preliminary note on a series of fifty cases which have been treated in Edinburgh under the auspices of the Corporation venereal diseases clinic. The majority of the cases have been treated in the wards of Edinburgh Royal Infirmary, the remainder in Corporation hospitals. This series differs from most others reported in that, without exception, the cases were first seen in the out-patient department of a venereal diseases clinic or in consultation in the medical wards of a general hospital. None of the patients was certified as insane; many of them were at the earliest stage at which the disease may be recognized; only a few were at an advanced stage, at which they might have been certified insane. The series includes a relatively high proportion of cases of juvenile general paralysis of the insane (28 per cent.). In practically all the cases under review, treatment by therapeutic malaria has been followed by the administration over a prolonged period of antiluetic drugs.

In treating these patients our aim was to secure lasting remission of the mental symptoms and restoration of physical vigour; as a result of the combined treatment success has been achieved in a gratifying proportion of cases. Accordingly, we have extended the use of this method of treatment since we started our work in 1927.

THE SCOPE OF THE REVIEW

Fifty cases are reviewed, and are classified as follows

General paralysis of the insane (adult)	...	28 cases
General paralysis of the insane (juvenile)	...	14 "
Tabo-paresis		6 "
Paresis sine paresi		2 "

The age periods of the patients were:

Up to 30 years	14 cases
30 to 40 years	12 "
40 to 50 years	14 "
Over 50 years	10

Of the adult cases 29 were males and 7 were females Of the juvenile cases 9 were males and 5 were females

DIAGNOSIS

Every patient had definite symptoms and signs of general paralysis of the insane, and the diagnosis was always confirmed by an examination of the blood and of the cerebro spinal fluid The Wassermann test was strongly positive in both blood and cerebro spinal fluid in every case In the majority, the cerebro spinal fluid showed a pathological increase of cells and globulin, and Lange's gold solution test gave a paretic or strong luetic reaction

SELECTION OF CASES

The cases selected for malarial therapy included

1 Cases showing pronounced mental symptoms and in which the disease was advancing rapidly

2 Cases of general paralysis of the insane which had received prolonged treatment with anti syphilitic drugs but had not responded favourably

3 Cases already advanced when first seen

Several patients in whom the disease was advanced, or who were seriously ill from other maladies, were included, even though the gravity of the prognosis was recognized It was considered that malarial therapy offered the only reasonable hope of improvement The patient in Case 32, for example, had a large aortic aneurysm, Case 44 suffered from severe diabetes mellitus, Case 40 showed marked dementia, incontinence, and bed sores

PROCEDURE ADOPTED

In every case a full neurological examination was made, and the blood and cerebro spinal fluid were examined A detailed physical examination of the patient was conducted, particular attention being paid to the circulatory system Blood films from a known case of benign tertian malaria were examined to ascertain the activity of the infection If malaria parasites were present in fairly large numbers, 3 to 5 c.cm. of blood were withdrawn by vein puncture and inoculated into the patient with general paralysis of the insane The most favourable time to withdraw blood is prior to the onset of the rigor or during a rigor The blood may be inoculated immediately into the recipient either intravenously or subcutaneously in the interscapular region, on the other hand, the blood may be citrated, kept on ice, and inoculated into a patient at any time within twenty four hours Every patient was confined to bed after inoculation, and a four hourly record of the temperature and pulse was kept After the first rise of temperature above 100° F. the temperature was recorded every two hours, and hourly during rigors If the patient was debilitated, or if there was any evidence of cardio vascular disease, appropriate tonics and cardiac stimulants were administered from the time of inoculation Iron was given in all cases to counteract the anaemia Very careful nursing was required

INOCULATION

Benign tertian malaria was used in all cases except one (Case 31) in which quartan malaria was inoculated Several different strains of benign tertian malaria were employed These strains had been used for the treatment of general paralysis of the insane for a considerable period The patients were inoculated either subcutaneously or intravenously, according to whether a long or a short incubation period was desired By the subcutaneous route the average incubation period from inoculation to the first rigor was fourteen days, with extremes of five and twenty two days, by the intravenous route the average incubation period was eight days, with extremes of two and fifteen days

INCUBATION

The incubation period did not vary with the volume of blood injected, but a heavily infected inoculum appeared to give a shortened incubation period Malarial parasites may be found in small numbers in the peripheral blood for several days before the first rigor Within twenty four or thirty six hours of intravenous inoculation there was in many cases a rise of temperature to 100° or 101°, lasting for about twelve hours This initial pyrexia was not seen in patients inoculated subcutaneously It has been suggested that such initial rises are due to haemo lysis in incompatible blood groups, but this did not appear to be the case in our series Further study of blood grouping in relation to inoculation by malaria is being made Patients who have suffered from a natural malaria infection in the Tropics can be inoculated successfully, and the disease seems to run the usual course Four of our cases had suffered previously from malaria, and one had had an attack of blackwater fever Some degree of immunity seems to be acquired after induced malaria, four of our cases however, have been successfully re inoculated after an interval of a year

OBSERVATIONS DURING THE COURSE OF INDUCED MALARIA

Type of Fever.—In many cases the malaria did not run a true 'tertian' course, often it assumed the quotidian type, or became quite irregular Quotidian pyrexia is very exhausting to the patient The tertian type is said to be commoner when the bloods of donor and recipient are incompatible Jauregg considers that the quotidian type of fever in induced malaria is due to particularly favourable conditions for the growth of the malarial parasites afforded by cases of general paralysis of the insane

Hyperpyrexia.—When the temperature exceeded 105° tepid sponging usually prevented further rise, and stimulants assisted the patient Quinine in small doses has been recommended as a means of controlling the fever, we have found that even a single dose of 1½ grains of quinine bi hydrochloride arrests the malaria In five cases in which this amount was given to control pyrexia, or to secure a longer interval between rigors, no further rise of temperature occurred

Symptoms.—Mental symptoms were aggravated in some cases during the rigors, and tabetic pains and crises were increased in severity Not infrequently the excited and exalted patient became subdued and depressed

Complications.—Albuminuria and gastro intestinal disturbances were not a prominent feature in our cases Herpes labialis was common Cardiac failure is the greatest risk of this treatment Enfeebled patients are very susceptible to broncho pneumonia In most cases, at the end of the febrile period the patient was exhausted, and hypodermic injections of stimulants were required A slight icterus was noticed late in the course of the fever in most cases, and the liver and spleen were increased in size in every case In two cases severe jaundice developed, and the malaria had to be terminated It is significant that both these patients had suffered from natural malaria in the Tropics, and one had had black water fever One of these patients was successfully

reinoculated one year later, and did not develop jaundice. The patients recovered rapidly from the jaundice as soon as the malaria was stopped, and they have been treated subsequently by tryparsamide without intolerance. The malaria parasites live on and feed at the expense of the red blood corpuscles, and the degree of anaemia is proportional to the severity and duration of the malaria. All our patients showed a marked anaemia, but recovered rapidly after the fever was terminated. Retention of urine was occasionally troublesome.

Termination of Fever.—Most patients were allowed to have twelve rigors, unless there were signs of cardiac failure or of other severe complication. In several cases the fever was spontaneously arrested after six to ten rigors, but even in such cases quinine or plasmoquine compound was administered to prevent subsequent relapses. The largest number of rigors allowed in any case was sixteen, while the average was 10.6. Quinine bi-hydrochloride orally or plasmoquine compound tablets (Bayer) were effective in curing the malaria. No malaria relapses have come to our notice. Our observations suggest that better results were obtained in cases having at least eight rigors. The absence of relapses after treatment of inoculated malaria confirms the observations of other observers (James[4]). On the other hand, malarial therapy induced by the bites of mosquitos is followed by a relapse in 50 per cent. of the cases after treatment. This is a very striking difference, and has important bearings on the epidemiology of malaria.[4]

Convalescence from Malaria.—Convalescence was generally very rapid, and with iron tonics, sunshine, and fresh air the patient was able to go about in three weeks in almost every case.

Immediate Effects of Malaria.—Clinically most cases showed a marked amelioration of symptoms, and their physical state was greatly benefited; two patients developed acute maniacal symptoms on terminating the malaria, but both subsequently made an excellent mental recovery. The influence of malaria on the serological changes was indefinite. In several of our cases the blood and cerebro-spinal fluid were examined a few days after stopping the malaria, and in all cases both blood and fluid were examined within a month of terminating the fever. The Wassermann test of the blood showed little alteration; the cerebro-spinal fluid changes were very variable, and did not correspond to the clinical condition. The pleocytosis, globulin content, and gold sol test were more favourably affected than the Wassermann test. Serological improvement has been observed to appear at a much later date than the clinical improvement.

Antiluetic Treatment

It has been shown—and our cases substantiate this view—that malaria does not cure the syphilitic infection, and that most cases of general paralysis of the insane have a progressive systemic infection and a pathological cerebro-spinal fluid even after malaria. Accordingly, we have tried to stabilize the improvement due to malaria by starting antiluetic treatment as soon as the patient is convalescent from malaria. In many cases the serological findings have shown progressive improvement during this subsequent treatment, and concomitantly the mental and physical state has been maintained or has steadily improved. Tryparsamide has proved effective in the treatment of neuro-syphilis, but is less potent in systemic syphilis. In view of this we have adopted a combined treatment with tryparsamide and bismuth simultaneously. Iodides are also given, and occasionally mercury, although, in our experience, mercury is more toxic and less efficacious than bismuth. The "914" compounds have not given good results in this type of case. The average amount of treatment in a period of six months has been 50 grams of tryparsamide intravenously, and 6 or 8 grams of metallic bismuth intramuscularly. The patient attends once weekly as an out-patient, and at each visit receives 3 grams of tryparsamide intravenously and 0.2 to 0.4 grams of bismuth intramuscularly. A course consists of ten weekly injections, and an interval of four weeks elapses between each course. During the interval iodides are given orally, and tonics may be required. This routine may be continued with advantage over a very long period; persistence is, in our opinion, the essence of the treatment, and our earliest patients have received very large amounts of these drugs—for example:

Case 1: Tryparsamide 361 grams, bismuth 44.4 grams, in five years.

Case 4: Tryparsamide 305 grams, bismuth 38.1 grams, in four and a half years.

Case 41: Tryparsamide 211 grams, bismuth 31 grams, in three years.

Both drugs have been tolerated well, and we have had no cases of toxic amblyopia or of optic atrophy following tryparsamide injections in general paralysis of the insane. Tryparsamide in moderate doses has a marked tonic effect after malaria.

Results of Treatment

It has been necessary to adopt a standard by which to estimate results. The following classification has been used for our cases:

A. *Complete Recovery:* There are no mental symptoms present, and the patient is able to resume his usual occupation.

B. *Partial Recovery:* The patient is free from mental symptoms, but is not able, from physical causes, to resume his normal occupation—for example, is incapacitated by ataxia.

C. *Improved:* Slight mental symptoms or physical signs present; patient is unable to work, but does not require institutional care.

D. *No Improvement:* Mentally and physically impaired, and institutional care required.

Grades A and B are considered satisfactory results, C and D poor results. In the following table all patients now dead are included, irrespective of the cause of death.

Table I

	Satisfactory (A and B)	Poor (C and D)	Deaths
	Per cent.	Per cent.	Per cent.
Whole series ...	28.0	54.0	18.0
Adults only ...	30.6	59.0	12.4
Juveniles only ...	21.4	64.3	14.3

Consideration of Successful Cases

Of the series, 14 patients (28 per cent.) showed complete remission of their mental symptoms and have returned to work. Four patients were not able to resume fully their normal occupation, owing in three instances to tabetic symptoms such as ataxia. Of the 14 successful cases, 11 were males and 3 were females; 8 were adult and 3 were juvenile cases of general paralysis of the insane, while 3 suffered from tabo-paresis. Their ages, which ranged from 20 to 60 years, did not appear to influence the result. The average duration of the syphilitic infection in these cases was seventeen years. The average number of malaria rigors was eleven, and the average period of observation of the successful cases following malaria therapy was twenty-two months.

The changes in the cerebro-spinal fluid as an immediate result of malaria were estimated as: marked improvement 3, slight improvement 3, no change 7, worse 1. Accordingly the immediate changes in the cerebro-spinal fluid were not a reliable guide to prognosis. All these successful

ul cases have had subsequent anti-syphilitic treatment. The present results as regards serological tests are seen below.

TABLE II.—*Serological Results in Successful Cases*

	C.S.F.	Blood	Both Blood and C.S.F.
Negative	7	5	2
Positive...	7	9	5

In five cases the blood Wassermann test is now negative, but the cerebro-spinal fluid remains positive. In no case has the cerebro-spinal fluid become negative while the blood has remained positive.

CLINICAL RESULTS IN OTHER CASES

In the patients who made an incomplete recovery there was in every case considerable physical improvement and some mental improvement. The patients, for example, were less excitable, became continent and clean in their habits, and were often able to go about in hospital. Tabetic pains were often relieved.

JUVENILE GENERAL PARALYSIS OF THE INSANE

Fourteen cases of juvenile general paralysis of the insane have been treated. It was to be expected that this group would be rather a barren field, but, as the figures show, quite a fair measure of success has been achieved. Some observers consider juvenile general paralysis of the insane as a contraindication to malaria therapy (Johnson and Jefferson[5]). The clinical picture was usually very definite —a young person who had become dull, stupid, backward, dirty in habits, careless, and unduly "childish." The clinical recovery in 21.4 per cent. of these patients, with a mortality of 14.3 per cent., justified this method of treatment, as otherwise the prognosis in such cases is progressive dementia and early decease. All juvenile patients improved physically, almost all regained control of their organic reflexes; and returned to clean habits. Drug treatment alone has not produced such gratifying recovery.

TABLE III.—*Serological Results in Juvenile General Paralysis of the Insane*

	Strong Positive	Weak Positive	Negative
Blood	9	0	3
Cerebro-spinal fluid	8	1	3

TABLE IV.—*Serological Results in Whole Series*

	Strong Positive	Weak Positive	Negative
Blood	32	2	10
Cerebro-spinal fluid	29	11	4

MORTALITY

In our series nine patients (18 per cent.) are now dead. Of these deaths three were not directly attributable to malaria. In Case 7 the patient died nineteen months after malaria from dementia and cerebral seizures; in Case 35 the patient committed suicide; in Case 19 the patient improved sufficiently to attend as an out-patient, then went on holiday, and three months later was found dead, the cause being unknown. Malaria, or intercurrent disease occurring during or very soon after the pyrexia, was the cause of death in five cases (10 per cent.). One patient died in hyperpyrexia; this was a very enfeebled case of juvenile general paralysis of the insane that had been inoculated with quartan malaria. Three cases showed an advanced degree of mental enfeeblement and physical debility, so that malaria was considered a grave risk; these patients developed cardiac failure and bronchopneumonia, and died shortly after terminating the rigors. One patient, aged 55, suffered from severe diabetes, and though he was carried though eight malarial rigors, he died three months later from diabetic coma.

As this series includes several advanced cases of general paralysis of the insane, and several cases of other serious disease, and as all deaths to date are included irrespective of cause, the mortality is not unduly high. When it is recalled that the death rate from untreated general paralysis of the insane is considerable, the treatment by induced malaria is not, in our opinon, an unduly dangerous procedure. This view is supported by results obtained by others, particularly in the clinic of von Jauregg in Vienna. Our observations have so far been in favour of this therapeutic measure, and we hope that by earlier diagnosis of general paralysis of the insane, and by applying this method to cases before marked mental changes are observed, even better results will be obtained. Further observation over a long period is essential before a final estimate of results is possible.

SUMMARY

1. Fifty cases treated (36 adults and 14 juveniles).

2. Successful result in 28 per cent. of cases (30.6 per cent. adults alone, 21.4 per cent. juveniles alone).

3. Mortality due to malaria is small (10 per cent.).

4. Induced benign tertian malaria is easily cured. No malaria relapses in this series.

5. Serological improvement in blood and cerebro-spinal fluid frequently observed.

6. Value of anti-syphilitic treatment following malaria. Both clinical and serological results often show progressive improvement.

7. Necessity for prolonged observation of all cases.

I am greatly indebted for permission to observe and report these cases to Mr. David Lees, and to the honorary physicians of Edinburgh Royal Infirmary, under whose care the patients have been. Colonel E. D. W. Greig, lecturer on tropical diseases, Edinburgh University, has observed nearly all the cases throughout the course of the malaria, and has given great assistance in the treatment, and very valuable help in the preparation of this report. Colonel S. P. James of the Ministry of Health has supplied us on several occasions with strains of malaria for use in this series.

THE FUNCTION OF THE ISOLATION HOSPITAL IN MODERN PRACTICE*

BY

E. H. R. HARRIES, M.D., D.P.H.

MEDICAL SUPERINTENDENT, CITY HOSPITALS FOR INFECTIOUS DISEASES; UNIVERSITY CLINICAL LECTURER ON FEVERS, BIRMINGHAM

Isolation hospitals are designed to isolate, until no longer potential sources of danger, those suffering from certain of the acute specific infectious diseases, with a view to the control of those diseases in the community. Since most of those so isolated are also physically ill, treatment of the illness occasioned by the infection is a necessary corollary.

The primary functions, then, of the infectious diseases hospital are the isolation and treatment of the infectious sick. The fact that in this country most of those sick from

* Read in opening a discussion in the Section of Public Health (including Tuberculosis and Occupational Diseases) at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

at least some of the acute specific infections are isolated and treated in special institutions should impose two other functions upon, at any rate, the larger of those institutions—namely, teaching and research. To what extent and with what success does the isolation hospital carry out its primary functions of isolation and treatment, and what may be termed, perhaps, its secondary functions of teaching and research?

The Isolation Hospital

To relate the story of the development of the present-day isolation hospital from the old pest house would be to relate a large part of the history of public health in the nineteenth century. Indeed, the Public Health Service arose out of the necessity of dealing in an organized manner with the then formidable endemic and epidemic acute infectious diseases which took such a considerable toll of lives.

At least from the days of Murchison, the 'sixties of last century, isolation hospitals have been considered an essential part of the equipment of sanitary authorities. Murchison's classical treatise on the continued fevers of Great Britain contains in its last chapter a discussion "on the relative merits of isolating fever patients and of distributing them in the wards of a general hospital." Murchison advocated the isolation of cases of fever in the separate wards of a fever hospital. Except for the modifications made possible by the various types of barrier-nursing, this is in general the practice to-day. With few exceptions, local authorities make provision for the reception of cases of smallpox in a separate institution and for such cases of the other acute specific infections as it is considered desirable by the medical officer of health to isolate in a fever hospital.

The degree of success attained by isolation as a means of control varies with the particular disease and with the particular local circumstances. There is general agreement about two things: the great value of isolating the first cases of an *epidemic* disease and the very small value of the same measure as a means of controlling *endemic* infectious disease. The recent advances in the knowledge of immunity and of epidemiology based in part upon those advances have shown why the hopes which were at one time held in regard to endemic infections were inevitably doomed to disappointment.

Stallybrass, in his admirable work on "The Principles of Epidemiology," recently published, writes as follows:

> "The great success of isolation against smallpox, typhus and, to a lesser extent, typhoid led the epidemiologists of the nineteenth century to a hope that they would be able to 'stamp out' scarlet fever and diphtheria in a like manner; in this they were deceived. The finding of numerous 'missed cases' of smallpox and typhus encouraged them to hope that by the search for such cases in scarlet fever and diphtheria they would still be successful in the 'stamping out' policy . . The numbers of temporary and chronic carriers (in these two diseases) render it improbable that complete success will ever attend a policy based entirely upon isolation and disinfection . . . In typhus, typhoid and smallpox the success of isolation was associated with other means of attack upon the means of transmission in the two former and by immunization in the last. It was at first hoped that isolation would prevent measles and whooping cough Owing to the high infectiousness of these two diseases during the prodromal or catarrhal stage they give rise to numerous secondary cases before the nature of the primary case is brought to light."

Need for Immunization

As is the case with smallpox, which in its present form threatens endemicity through the neglect of vaccination, there is only one rational method of controlling these endemic diseases—the active immunization upon a sufficient scale of the susceptibles; in this country, a degree of perfection. A measure of achievement and disease is slowly being attained in the case of diphtheria, a disease which the public fears. In the case of scarlet fever means exist, but the necessity for their employment on any large scale can hardly be said to exist while the disease retains its present mild characteristics. As for measles no method of active immunization is so far available, and upon any sufficient scale, proved as this is, neither temporary passive immunization nor attenuation of the attack by the use of human serum is practicable. The supply of human serum is always likely to fall hopelessly short of the demand. Whooping cough, probably at present the most damaging of all the acute specific infections of childhood, not excepting measles, at least merits trial upon an adequate scale of prophylactic vaccines used with such success by Madsen in Denmark.

Although the failure of isolation of the endemic infections as a communal measure has to be admitted, there is hardly in question that in special circumstances and in individual instances the removal and isolation of a focus or source of infection is a necessary procedure. Nobody would propose that a case of enteric fever, scarlet fever or diphtheria occurring above a milk shop should remain to be nursed at home. A case of scarlet fever or diphtheria occurring in a residential children's institution must almost inevitably be removed to hospital. Needless to add, this step should be followed by the appropriate measures available for the discovery of other potential sources of infection and for the detection and protection of the remaining susceptible inmates. There are many environmental circumstances which make institutional isolation necessary. Added to them are the social and economic difficulties so often created by the occurrence of a case of infectious disease in the home.

Isolation of the Suspected Case

Its limitations admitted, the isolation hospital, from the point of view of preventive medicine alone, justifies its existence as part of the equipment of the sanitary authority and is likely to do so indefinitely. But this is not to agree that the available accommodation of the isolation hospital is always used to the best possible advantage. *Numbers of patients are admitted* without sufficient justification from the standpoint of either preventive or curative medicine.

The isolation hospital is unique among hospitals for the reception of acute diseases in that it admits to its wards a large proportion of cases sent directly by the general practitioner. There is no intervening casualty or out-patient department. A receiving room there may be, but this is in the nature of a distributing centre for the wards. Cases examined in the receiving room, even if the provisional diagnosis be patently incorrect, are always admitted to one or other of the isolation wards for observation.

Unless it were possible for each notified case to be seen at home in consultation with the practitioner it is difficult to see how the present method is to be avoided. The general practitioner acts for the best in difficult circumstances and in good faith is not for a moment questioned. Nevertheless, there does result the needless isolation of large numbers of adults and children, and, at times, undue pressure upon the available accommodation. This has been the case in diphtheria. In 1929, there were admitted to the Birmingham City Hospitals, 2,099 cases with a diagnosis of diphtheria; 706 (33 per cent.) presented evidence of clinical diphtheria upon admission to hospital. In 1930, 2,162 cases were similarly admitted, of which 739 (34.4 per cent.) showed no evidence of clinical diphtheria. Fully 50 per cent. of these revised cases had been

in purely as a result of a report upon a swabbing A considerable proportion of them proved to be Schick negative or immune to diphtheria on admission In the great majority the swabbing when repeated was negative or the organisms present were shown to be avirulent Investigation of these cases—with the Schick test and with virulence tests—occupies on the average ten days, at the end of which period the patients are discharged Meanwhile valuable beds are occupied, and the patients, especially the adults, suffer considerable social and economic inconvenience The value of the swab in the diagnosis of diphtheria is over estimated to the same extent as the value of a timely dose of antitoxin *on suspicion* is underestimated

It is also peculiar to isolation hospitals that, unless a separate convalescent hospital is available, these institutions have to retain their convalescents, not only on the grounds of physical unfitness, but because of the presumed danger of infection in convalescence That this danger has been greatly overrated in the past is shown by the fact that although the period of detention of cases of scarlet fever is being steadily reduced there is no rise in the return case rate, but rather the contrary, and that those hospitals which discharge their diphtheria cases without the ritual of swabbing similarly cannot be charged with increasing the proportion of return cases

TREATMENT

Some infections, however good the environment and the means of isolation it is hardly possible to treat with the maximum chances of success elsewhere than in an institution In the case of other infections like rubella and chickenpox, poorness of circumstances and even lack of treatment altogether cannot be said to make much difference to the ultimate result Morbidity in these conditions is trifling and mortality nil It is hardly in dispute that any case of clinical diphtheria, as distinct from a transient carrier state unless of the very mildest is better treated in hospital if there is not ample provision of skilled nursing in the home Scarlet fever provides matter for controversy In spite of a very high isolation rate the disease is as prevalent as ever Is it necessary to remove to hospital for the purpose of treatment the high proportion of notified cases which at present, in some places at least, is so removed? Could not many of these cases be as well treated at home, especially now that the disease is so mild and that a specific antitoxic therapy is available which is capable of simplifying the management of the case considerably? Could not many of the beds now occupied by cases of scarlet fever be better utilized for the reception of other infections of more serious import?

Strictly from the point of view of the possibility of treatment, many would agree that this is so, but there are two other factors which have to be taken into consideration First, the public, in many towns at least, expects a case of scarlet fever to be removed to hospital, it always has been so removed Secondly, the necessity of attendance upon cases of scarlet fever must frequently prove an embarrassment to the practitioner who has a large midwifery practice Hence, however feasible theoretical reasons may be, practical factors may combine to make attainment a matter of great difficulty It is largely a question of re-educating a public which at one time was forcibly impressed with the necessity of the hospitalization of scarlet fever, then a severe disease In contrary sense the same holds good for measles and whooping cough Here, the public needs to be impressed with the gravity of these diseases, and with the fact that for the adequate treatment of many cases removal to hospital is essential.

Modern Methods

In the old days treatment of the fevers was wholly expectant The introduction of diphtheria antitoxin in 1894 was the first nail in the coffin of the expectant treatment of the acute specific infections Treatment, in addition to becoming more rational, has in many cases become more complex, and necessitates a specially trained medical and nursing staff and a hospital adequately equipped for its task Team work is as essential in a fever hospital as in any other To take one example Recent work has shown that the treatment of severe toxic diphtheria, if the best results are to be obtained necessitates not only an adequate dose of antitoxin, absolute rest, and skilled nursing, but repeated estimations of the blood sugar The administration of dextrose and insulin is based upon these estimations, and, in order accurately to gauge the condition of the muscular and conductive tissues of the heart serial electrocardiograms are necessary For this work the co-operation of three medical officers is required By these measures the case mortality of the worst examples of toxic diphtheria, when compared with an adequate series of controls, has shown in the Birmingham City Hospital a reduction of nearly 13 per cent

The modern treatment of some at least of the acute specific infections necessitates an equipment and a technique as complete as that required in the treatment of diseases other than the fevers The hospital entrusted with the care of the infectious sick should attain, and in many cases does attain, to a standard no whit inferior in any respect to that of a good general hospital Where this standard is unattainable by reason of smallness of size or meagreness of staffing, the solution lies, of course, either in the abolition of very small hospitals and the erection of large centralized hospitals served by motor transport, or in the provision for the reception of infectious cases in a block of the local general hospital Both these measures are in fact in process of adoption

TEACHING

The admission as a general procedure of cases of infectious disease to blocks attached to general and children's hospitals, although a common arrangement on the Continent and in America, is unusual in this country In large cities at least, the high hospitalization rate of cases of infectious disease would make such an arrangement, except as a partial measure, impracticable

As a result of the advice originally tendered by Murchison, practically all general and children's hospitals possess isolation blocks, but these are in the nature of emergency accommodation Most of these institutions continue to admit the enteric group of infections and the acute infectious diseases of the nervous system These diseases are commonly treated in the ordinary medical wards It is on the whole correct to say that the vast majority of cases of the common fevers, if treated in hospital at all, are treated in isolation hospitals The consequence is that these institutions have a virtual monopoly of the material necessary for the clinical teaching of fevers Unless adequate use is made of this material it is bad for medicine, preventive and curative With one exception, the historic London Fever Hospital, which remains as it began, a voluntary institution with an honorary as well as a resident staff, the fever hospitals in this country are controlled by public health authorities and staffed by medical officers in the service of those authorities The large institutions have a medical superintendent and several assistant medical officers the smaller have resident medical officers who may also have other public health duties, the smallest may be in charge of the local medical officer of health and may have no resident medical officer at all.

During the last few years several of the large fever hospitals have appointed stipendiary specialist visiting staffs—for example, otologists. Some also have appointed consulting general surgeons and physicians for occasional operative or consultative work. Generally speaking, the whole of the clinical material is under the care of resident medical officers. After a longer or shorter stay most of these medical officers pass on either to some other branch of the public health service or to general practice. Their numbers are, relative to the whole profession, infinitesimal. Except for this small number of practitioners with special post-graduate hospital experience of fevers, such clinical knowledge of the common fevers, which form such an important part of preventive and curative medicine, as the recently qualified practitioner obtains, he obtains almost wholly as the result of a breathless series of visits, quite inadequate in number, to the wards of a fever hospital. These visits are sandwiched in with some difficulty between half a dozen special subjects in the final year.

Inadequacy of Instruction

Even upon the score of making the most economical use of the available beds by a reduction in the percentage of cases unnecessarily admitted, it is essential that the young practitioner should receive more adequate instruction in the diagnosis of fevers than is at present possible. By some means, the wealth of clinical material in the large fever hospitals should be made available for thorough undergraduate and post-graduate study. The isolation hospital should not be separated from the general stream of medicine. It is bad for medicine and for its practitioners, whether within or without the walls of the institution. In provincial university cities, the medical superintendent of the fever hospital also holds, as a rule, a clinical lectureship on fevers in the university, and it is he who gives such clinical instruction in the wards as present circumstances permit. Why should not the medical student clerk in the wards of the fever hospital, if only for a brief period? Why also should not the young general physician attached to a children's or general hospital be also attached for a term to the staff of a fever hospital and take part in its work and teaching? Administrative difficulties there might be, but difficulties exist to be overcome. There is little doubt that with sufficient breadth of view on both sides smooth working could be secured. Of the advantages to medicine, if these suggestions became accomplished facts, there is no doubt whatever. The end justifies the means.

Research

The fact that the isolation hospital has a virtual monopoly of clinical material imposes upon it not only the duty of dissemination in the most effective manner of the knowledge already gained of fevers, but also the duty of advancing knowledge. The study of the fevers of temperate climates is passing, as did the study of tropical fevers under the stimulus of Manson, from the stage of clinical description and empirical treatment to that of the scientific investigation of cause and mechanism, with the resultant provision of rational preventive and therapeutic measures. The war provided a powerful lever no doubt, but the work of Schick, published, as a matter of fact, in the year preceding the outbreak of war, was the first series of notable advances in immuology.

Paucity of Research in England

What have been the contributions of the fever hospitals of this country to all the recent advances which have been made? To original research, the contributions have been small indeed. The contributions of the fever hospitals to the advancement of knowledge of the diseases with which they are particularly concerned have been [illegible] the nature of repetitive work. The repetition, however necessary and however meticulously and laboriously carried out, of work originated by others with means provided by others is not research; it is merely a checking of the research of others. Here and there an exceptionally able and industrious medical officer has under great difficulties achieved a piece of original investigation. But for the rest, the work, again, it is true, carried out under great difficulties and sandwiched between routine duties, has been repetitive. Save that provided by the occasional thesis, usually stillborn, there is no stimulus to research in the fever hospital, no official recognition of such a possibility being possible, and, with few exceptions, no suitable equipment available. A perusal of the Continental and American literature of the acute infections is from every point of view depressing. The output of original investigation, scientific and clinical, of foreign institutions to which infectious diseases are admitted is continuous, and maintained it of the highest standard. Owing to the high hospitalisation rate of fevers in this country, the clinical material is relatively more abundant here than elsewhere.

Possible Lines of Research

The contributions which the fever hospital might make to the advance of knowledge are not only direct but also lateral. Children form the majority of its patients—children, too, who except for the acute infection from which they are for the time being suffering are essentially healthy. The reaction of the hitherto healthy organism to infection can be studied in the child unaffected by other pathological factors which so frequently exist in the adult.

There is little doubt about the importance of the contribution which the fever hospital might make, for example, to the study of the earliest phases of rheumatism. Among the cases sent in with a diagnosis of diphtheria, many are suffering, not from an infection with diphtheria bacilli, but from tonsillitis due to other organisms. This initial tonsillitis is followed, not infrequently, by rheumatic manifestations—possibly the first manifestations in a young child. The fever hospital is practically the only institution in which cases of tonsillitis come under observation as in-patients.

Need of Organized Research

If the views put forward above are accepted, definite provision of personnel and equipment must be made for organized research, preferably in close association with the university and medical school in order that there may not be unnecessary overlapping. Among the existing young medical officers in the fever hospitals' service are to be found those who possess the necessary temperamental make-up for research. They only need encouragement and opportunity to produce good work. They could give of their best if they are swamped with routine duties. Such medical officers, duly approved by some independent board or committee, should be set free to do a definite piece of original investigation in the hospital to which they are attached. To their number might with advantage be added, from time to time, investigators from outside, young men and women who might be attached for a definite term to carry out a definite piece of work. Alternatively, those who apply for existing research facilities might consider the field, so far practically untilled, of the hospitals for infectious diseases present.

These institutions cannot be said so far to play the part they should and could play in advancing preventive and curative medicine. The personnel and the material are there; ways and means have largely to be created.

BATHING AND AURAL DISEASE

BY

JOHN E G McGIBBON, M B, B S, D L O

AURIST AND LARYNGOLOGIST EYE AND EAR INFIRMARY LIVERPOOL; ASSISTANT AURIST AND LARYNGOLOGIST, ROYAL SOUTHERN HOSPITAL LIVERPOOL

In an article contributed to the *British Medical Journal* of August 17th, 1929, by Drs W I Daggett and R Cove Smith, attention was called to the risk of acute aural disease caused by bathing A letter dealing with the same subject appeared in the *Lancet* of July 27th, 1929, and this provoked some correspondence on the prevention of pollution of public swimming baths In both of these contributions the authors expressed the opinion that the entrance of infected water into the Eustachian tube and the middle ear cleft was largely responsible for the incidence of this type of ear disease, the water borne infection in these cases being derived from contamination of public swimming baths and "town" rivers Further, they emphasized the fact that individuals who bathed whilst suffering from perforated drumheads or septic nasal conditions were a possible source of danger to themselves and to other bathers

These observations led me to examine the record sheets of all cases of acute aural lesions attributed to bathing, and seen by me during 1930 Seventeen cases were examined, and although the number is small it is possible to draw some conclusions from the series Of the seventeen patients twelve had bathed in public swimming baths and five in the sea

In a large industrial city such as Liverpool the proportion of bathers who use public swimming baths is far in excess of those who bathe in the sea, certainly a much greater ratio than 12 to 5 Furthermore, the sea bathers had all availed themselves of the advantages of the South Lancashire and North Cheshire coasts, and had bathed in the open sea, far away from sewage or other pollution of the water

In sixteen of the cases either there was present some aural abnormality or else there was some existing adjacent focus of infection in the upper respiratory tract These adjacent foci of infection were all gross lesions that were noted at the time of examination They all called for surgical treatment, which was advised, and which in several cases was carried out subsequently They were not sought after for the sake of obtaining statistics, and their constant presence only became apparent when the case records were reviewed

The existing adjacent lesions which occurred either singly or together were as follows

Lesions	No of patients
Previous aural lesions	7 (2 sea, 5 bath)
Pathological tonsils and/or adenoid	10 (4 sea 6 bath)
Marked septal deviations	5 (2 sea 3 bath)
Chronic suppurative ethmoiditis	1 (bath)
Hypertrophic rhinitis	1 (bath)
Acute coryza	2 (bath)

The accompanying table shows the results more graphically All the cases were in males, except No 15

Case 1 is the only "healthy" bather in whom there was no evidence of previous aural disease or of an existing adjacent focus of infection Case 5 is interesting, as the patient's elder brother had undergone a simple mastoid operation two years previously, owing to an acute mastoid itis which developed after bathing Three patients underwent paracentesis

The table shows also that the interval between the time of bathing and the onset of symptoms was some hours less in those patients who had suffered from previous aural disease than it was in those who showed only an adjacent infective focus

No	Age	Aural Lesion	Previous Aural Lesion	Existing Adjacent Lesion	Date of Onset	Sea or Bath

Conclusions

1 A series of seventeen patients who suffered from acute ear disease attributed to bathing is reported Of this series sixteen patients had suffered from a previous aural lesion and/or some existing abnormality of the neighbouring upper respiratory tract

2 The proportion of bathers in this series who contracted ear disease is relatively greater amongst the "clean" sea bathers than it is amongst the 'polluted' bath bathers

3 In view of conclusions 1 and 2, it may be assumed that acute aural disease following bathing is usually an autogenous infection, and occasionally only is it caused by infection derived from the water of public swimming baths

4 In addition to the measures of personal and public hygiene advocated by Daggett and Cove Smith, it is advisable, though maybe impracticable, that any individual who contemplates bathing should be examined at least once by a doctor *re* the condition of his ears nose, etc This latter measure certainly could be carried out during the routine examination of school children

5 Any individual found to be suffering from aural, nasal, or pharyngeal abnormality should be warned of the danger attached to bathing in either the sea or in swimming baths

MEDICAL, SURGICAL, OBSTETRICAL

A CASE OF POISONING BY SODIUM NITROPRUSSIDE

Although it is well known that sodium nitroprusside is a powerful poison, we have been unable to find record of any cases of human poisoning by this substance. Glaister[1] in his textbook make no reference to the subject; Sollmann[2] gives a brief quotation from L. Hermann, in which it is stated that "nitroprussides liberate CN readily and agree with cyanides except that they are less convulsive." Wynter Blyth[3] gives an account of some work by Reid Hunt in which the toxic dose of many cyanides, including sodium nitroprusside, was determined when injected subcutaneously into mice.

The absence of cases of human poisoning by sodium nitroprusside is not difficult to understand. It is a material which is unknown to the general public. Its principal use is as a reagent in certain important chemical tests. Hence those who have access to it have generally sufficient knowledge of toxic substances to prefer some other poison, if suicidally inclined.

The case about to be described was that of a student of chemistry. At about 2.10 a.m. he called out from the garden of his lodgings to a fellow boarder within the house that he was poisoned. The person spoken to at once went out to his assistance, and found him unconscious. A doctor was immediately sent for. He found the patient still unconscious, slightly cyanosed, with froth at the mouth and slight dilatation of the pupil. There was no characteristic smell in the breath nor burns about the mouth. The patient was immediately sent to the Leeds General Infirmary. On admission the condition of the patient was similar to that already described. Respirations were slow, irregular, and heavy, with short inspiration and prolonged expiration. The pupils were moderately dilated and reacted sluggishly. The temperature was 97.6° F., and the pulse 60. Death occurred at 4.40 a.m. No convulsions were seen at any time.

A post-mortem examination was made at 10 a.m. by Dr. Ella M. Hickman. On opening the body the smell of HCN was definitely detected, and all the evidence was consistent with cyanide poisoning. The stomach contents were removed in a stoppered bottle for separate examination. On removing the stopper after a short interval the smell of HCN was also readily detected here, and the presence of HCN in the air immediately above the fluid in the bottle was demonstrated by chemical tests.

In attempting to decide on the exact nature of the poison which had been taken, we soon excluded free hydrocyanic acid. The very definite smell of HCN on opening the body, and again frequently detected while handling the organs, and also evolved from the stomach contents, indicated that a very considerable dose of a cyanide had been taken, and if this had been in the form of free HCN death would have occurred much more rapidly than was actually the case. Death also appeared to have been unnecessarily delayed even if the material taken had been a simple cyanide. While considering this point it was found that a bottle containing a liquid solid salt (57 grains per ounce). When the stomach contents were examined for the presence of nitroprusside strongly positive reactions were obtained. Poisoning by sodium nitroprusside appeared to us, therefore, to be definitely established.

The interest of this case lies in the fact that the symptoms before death, and the appearances after death, were those of hydrocyanic acid poisoning, but the time which elapsed after taking the poison before death occurred—namely, at least two and a half hours—was considerably longer than is the case when very large doses of the simple cyanides are taken. The effects are, of course, actually due to free hydrocyanic acid, which is produced as a result of the decomposition of the nitroprusside, and the time required for this decomposition to occur within the body accounts for the delay in the occurrence of death. But although this delay does occur, the rate at which HCN is produced from nitroprusside within the body is greater than one would expect from a knowledge of the behaviour of this substance *in vitro*. It is well known, for example, that aqueous solutions can be kept for long periods without the appearance of free HCN. H. E. Williams,[4] in an account of the chemistry of nitroprussides (nitroferricyanides) states that solutions of the sodium salt can be evaporated without decomposition, and our own experience verifies this statement. Of reactions which produce free HCN he mentions reduction in neutral solution with a copper-zinc couple, and reduction in sulphuric acid solution with sodium amalgam. Both these methods of reduction are fairly powerful ones, but the results of ingestion of sodium nitroprusside, as exemplified in the present case, certainly indicate that in the stomach, and possibly elsewhere in the body, reduction of this substance, with the production of free HCN, must be a fairly easy and rapid process.

The experience of this case also suggests that in cases of cyanide poisoning, where death appears to be unduly delayed, unless definite evidence of the use of a simple cyanide is forthcoming, the possibility of a complex cyanide having been taken should be explored.

F. S. Fowweather, M.D., M.Sc., F.I.C., D.P.H.
Reader in Clinical Chemical Pathology, University of Leeds; Chemical Pathologist, Leeds General Infirmary.

RUPTURE OF POSTERIOR CEREBRAL ARTERY

The recent reports in the *Journal* of cases of "congenital intracranial aneurysm" prompt me to submit the following case.

On November 14th, 1930, an unmarried woman, aged [illegible] years, seamstress, always of a delicate constitution and a victim of indigestion and obstinate constitution, when stooping to fasten her shoe felt a sharp pain in the back of her head, with accompanying disturbances of vision, which passed off in a few days. A similar experience under identical conditions occurred on November 27th. She went to work as usual on November 28th, but had to return home because of disturbed vision. I saw her on this date, when there was complete oculomotor paralysis of the right eye, with ptosis and a fixed dilated and immobile pupil—the eye could be slightly rotated inwards. There was also pain in the back of the head, increased by forward bending of the head, but no rigidity of the neck, and Kernig's sign was absent. Confined to bed, she remained in this condition until December 16th, when she was very sick, and having a severe headache, she awoke [illegible] about 4 a.m. I saw her at about 5 a.m., when she

already unconscious. Coma supervened, and death took place at 10 a.m. Between 5 and 6 a.m., by lumbar puncture, I removed some cerebro-spinal fluid, which was deeply stained with blood.

Post-mortem examination of the brain revealed an extensive basal haemorrhage, which extended also down the spinal canal. This was the result of a rupture of the right posterior cerebral artery close to the bifurcation of the basilar artery into the posterior cerebral arteries. The third nerve at this point was severed, all but the merest strand.

Ramsbottom, Lancs. H. LAWRIE.

Reviews

MEDICO-CHIRURGICAL PRACTICE

Edited by a distinguished triad of the Faculty of Medicine of Paris, the third edition of *La Pratique Médico-Chirurgicale*[1] is heralded by the issue of the first four volumes. The complete eight volumes will provide a compendious encyclopaedia embracing medicine, surgery, obstetrics, and the ancillary specialties, written by 220 collaborators, each of whom is an exponent of the first rank in his particular subject. Avoiding hypotheses and theoretical discussions, the work provides a straightforward practical guide for the practitioner in etiology, symptomatology, diagnosis, prognosis, and treatment, with praiseworthy conciseness, but with sufficiency of detail. Extreme delicacy of judgement is required in such a work to maintain suitable balance as regards the subject-matter. On the whole, this has been attained in the volumes before us, except in the treatment of the majority of pharmacological subjects, which is too brief to be of value. Avertin, for instance, is dismissed in six lines. The photographic and *x*-ray plates are excellent, but the pathological line drawings are not in keeping with the general standard of the work. The figures dealing with dental anaesthesia (p. 455 et seq.) are most obscure.

The authors give essentially the modern French outlook, and the British reader will be impressed with the space afforded to psychiatric subjects. From the numerous subjects dealt with in volumes i and ii we would specially commend those on the surgical treatment of bronchiectasis (Dr. Oberlin), Caesarean section (Drs. Portes and Couvelaire), and the surgery of angina pectoris (Drs. Leriche and Fontaine). The section on the biliary system affords delightful reading, but most British surgeons will find fault with the unqualified statement that in acute appendicitis the pain "is most commonly located in the right iliac fossa, but sometimes in the umbilical region." The vexed question of antisepsis *versus* asepsis is summed up under the aphorism that, "while opposed in theory, they are ultimately combined in practice, and their union authorizes the bold technique of actual surgery." The sections on actinotherapy, on the arsenobenzols, and on artificial limbs are well written, and that on massage and remedial exercises is admirable.

In volumes iii and iv goitre is dealt with in a comprehensive manner, but the purely medical treatment of exophthalmic goitre is too theoretical for inclusion in an encyclopaedia such as this. Hydrotherapy, thermal treatment, ergotamine, sodium salicylate, haematoethyroidin, etc., ought to be omitted and replaced by some practical details about the administration of iodine and quinidine. The field of hygiene and public health has received ample attention. No fewer than eighteen pages are devoted to consideration of drinking-water (*eau potable*). The articles on dermatological subjects are well written, affording clear clinical descriptions and classifications, suitably illustrated by intelligible photographs. Eczema is differentiated from "eczematoid" conditions, the clinical entities of these groups being well substantiated.

The aim of the work tends to preclude much novelty and originality, but while treating the majority of subjects along conventional and, usually, orthodox lines, the collaborators have shown much originality in presentation of the facts, especially in the domain of surgery. Gastric and cerebral surgery are noteworthy examples. In view of the fact that modern surgeons are not likely to consult a general encyclopaedia to any extent, one wonders whether such works should not confine themselves solely to the sphere of the general practitioner, who, to take one example, is not likely to be ordinarily interested in the merits and technique of the operative methods used for diaphragmatic hernia. On the other hand, the present work very properly expounds such dentistry as commonly falls to the lot of the busy medical practitioner, and the clear methodical account of teeth extraction is worthy of emulation by most British authors of surgical manuals.

MEDICAL MYCOLOGY

It is a difficult thing for the medical man to obtain a comparatively brief yet adequate account of the moulds, yeasts, and related fungi which are of interest to him as causes of disease, or contaminations of his cultures, or are concerned in the spoilage of foodstuffs. There are, it is true, extensive monographs dealing with particular groups, but, apart from the detail they contain, their understanding implies a wide knowledge of mycology. Textbooks of bacteriology are too inadequate in their treatment of the subject to be of much use. Accordingly the time is ripe for a handbook[2] such as Professor HENRICI has now written. It has grown out of a lecture course which he has been giving for some years past to advanced students of bacteriology at the University of Minnesota, and, while making no claim to an exhaustive treatment of mycology, it clearly places before the medical and other bacteriologists all that they need know about the subject.

Beginning with a description of the structure and classification of the fungi, their methods of study, and biological activities, the author goes on to consider the more important groups of moulds, yeasts, and actinomycetes. When we recall that these groups include the causal organisms of the ringworms, thrush, actinomycosis, as well as a considerable number of tropical diseases, it is plain that a knowledge of the subject, however slight, is essential to every medical man. It is daily becoming more obvious that at least a number of bacteria belong to the fungi, and there is a well-defined movement to trace in the bacteria life-cycles and sexual relations similar to those found in the fungi; and so the bacteriologist also must be acquainted with the essentials of mycology—quite apart from a natural curiosity about the contaminating moulds which so frequently crop up in his cultures. Professor Henrici has supplied this need. The book is easily understandable by the beginner, and it is fully illustrated both by photograph and by line drawings. For those who wish to follow up any particular aspect of the subject there is a comprehensive bibliography. We have no hesitation in drawing attention to the usefulness of this volume to the bacteriologist and the physician. It is an excellent production, and most opportune.

PATHOLOGY OF CHEST DISEASES

Dr. N. P. TENDELOO's work, entitled Studies on the Mode of Origin and the Course of Diseases of the Lungs,[3] is an attempt to relate the localization and development of pulmonary diseases to the varying physiological conditions prevailing in different parts of the lung. In the normal lung he finds that the movements of the alveoli during respiration are least in the paravertebral cranial portion and greatest in the lateral caudal portion; that in any part of the lung the changes in alveolar volume are always greater in the peripheral than in the central portion; that the movement of the blood, and probably of the lymph too, is least in the suprathoracic and greatest in the caudal portion of the lung, and that it is proportional to the respiratory excursions. These processes are subject to variation with age, the shape of the thorax, occupational position, intrathoracic tumours, and numerous other factors. A discussion of their importance in determining the origin and location of such diseases as emphysema, pneumonoconiosis, and tuberculous and non-tuberculous inflammatory conditions of the lung occupies the greater part of the book. Many of the views expressed are of considerable interest, and will not fail to excite the attention of those whose chief study is the pathology of chest diseases.

DIET IN DISEASE

Harrop's *Diet in Disease*[1] forms an addition to the long list of books, for the most part of American authorship, which deal with diet. It is written from the standpoint of the practising physician, and for that reason must command respect. Part I, comprising the first four chapters, deals with the nutritional requirements of the body. Part II deals with the chemical composition, modes of preservation, and cooking of some of the staple foodstuffs. The third, and by far the longest, part is devoted to the dietary treatment of disease.

Opinion about the various dietetic measures which should be used in the treatment of various pathological conditions is in such a state of flux that no book of this kind can hope to escape criticism. Everyone is agreed about the great importance of dietetic measures, no two persons about the exact form which they should take. On the whole, it is clear that Dr. HARROP takes a broad-minded and conservative point of view, and clearly he bases his opinions upon the fundamental facts of biochemistry and, without doubt, upon personal observation. Fault may be found, perhaps, with his treatment of the subject of diabetes. On page 260, for instance, he says that it is highly doubtful "whether the fundamental diabetic process is often really altered or improved as a result of dietary treatment or the use of insulin," and from what has gone before it is clear that he is thinking not only of human diabetes, but also of experimental diabetes in animals. Now since ligature of the pancreatic duct with degeneration of the secreting gland tissue (and survival of the islets) does not cause diabetes, while pancreatectomy does cause the disease, and since all the signs and symptoms of such experimentally produced diabetes can be abolished by insulin, it seems wrong to speak of a "fundamental diabetic process" which is untouched by insulin; or, if such a phrase is used, then the burden of proof of its meaning rests on the speaker. It may be that in clinical diabetes there is something more than current views take count of; if so, it is a matter for investigation. The assumption of existence lays the author open to the charge of loose thinking.

In his further discussion Dr. Harrop gives the impression of not having grasped the distinction between acidosis and ketosis; he frequently uses the terms as if they were synonymous. Recent work, however, has certainly failed to establish a definite relationship between diminution of blood alkali reserve and the onset or depth of diabetic coma, or, for that matter, to prove conclusively that coma is due entirely to the presence of ketone bodies in the blood. We cannot help feeling that this part of the subject might have been approached with more caution. On page 341 appears the statement "feces are usually only passed once a week in the an animal fed only on meat." The writer of this has addressed an inquiry about this point to the curator of mammals at the Zoological Gardens, who was good enough to reply in the following terms: "Our experience with the animals fed entirely upon meat here is that they pass faeces very regularly once a *day*, and usually at the same time each day." Apparently Dr. Harrop has been misinformed on this point.

Although open to certain criticisms, the book is ably written, and will certainly prove of great value to the general physician.

A NEW PHILOSOPHY

Everyone, consciously or unconsciously, makes his own philosophy, but an intelligent and considered statement of the philosophy evolved by another may at times be of the most material help in filling out one's own, or in making it more satisfying, or even, on occasion, in settling or altering the essential basis on which it is constructed. A quite original and well-thought-out statement of this kind will be found in a volume, entitled *A Philosophy of Reality*,[5] by Miss E. L. YOUNG, recently published by the Manchester University Press. It seems likely to prove a very important book, and is one which should certainly be read and considered by all who desire to make their foundations sure and to think correctly in this sphere. It is impossible to epitomize a philosophy of such a kind in a column, or to indicate its fundamental idea adequately in a sentence; but, as is indeed suggested by the appropriate title of her book, the basis of Miss Young's belief may in a very general way be stated to be that things are actually what they seem, however much more they may also be; and that this must be so because every unit of matter or energy—the electron, the atom, the molecule, the cell—in its own primitive way and in its own limited degree, and within its own range, feels and experiences in a manner comparable to that in which the larger units formed of such units (plant, animal, or human) experience and feel. The philosophy of reality can therefore be contrasted with the two main currents of what may be called the philosophy of exclusively abstract thought, and the philosophy of doubt. It may be said to place emphasis upon the known, rather than to indicate that certain things—whether a "thing-in-itself," or something else—are unknowable.

But "I do not wish to suggest that we are able at present to know and to understand everything that the universe presents. If the objective world is an open book [for us], a face of truth, hiding nothing from us, I do not read every page of the book has been read or can be read at the moment. I do mean that the common man has already read much that is true, and the philosopher is in the way when he tells him to discard it and look for cryptograms and occult meanings."

---

[3] *Studien über die Entstehung und den Verlauf der Lungenerkrankungen*. Von Dr. N. Ph. Tendeloo. Zweite umgearbeitete und vermehrte Auflage. München: J. F. Bergmann. 1931. (Pp. viii + 219, 6 figures. R.M.26.)

[1] *Diet in Disease*. By George A. Harrop, jun., M.D. Philadelphia: P. Blakiston's Son and Co., Inc. 1930. (Pp. ix + 404. 4 figures.)

[5] *A Philosophy of Reality*. By E. L. Young. Manchester University Press. 1930. (Pp. vi + 266. 8s. 6d. net.)

In opposing any kind of illusionist philosophy the author well says:

"The highest type of mind is that in which the intensive thought can be given the most extensive application. The highest spirituality is shown by its power of filling the commonplace with more of meaning and value, and of turning without any sense of loss from the inner to the outer, and back again at will. A theory which tends to put reality into the sensations of matter, if it is tenable at all, will hold its own in the struggle for life of ideas themselves, against any theory which empties the concrete of a part of its interest."

Any attempt to show thus crudely what the author's theory is, and to what it is in essence opposed, is really to do the author an injustice. The main thoughts of the book are, as has already been said, original, and have been worked out and applied with extraordinary skill. After a general statement of the foundation of her philosophy, Miss Young applies it in successive chapters to "The Market of Matter," "The Human Unit," "Spiritual Life," "The Five Senses," "Time," "Space and Number," "Good and Evil." It is scarcely to be expected that any one reader will find all these applications equally or completely satisfying, even if the basis be accepted. Here and there, there may be some criticism as to her statement of the facts of physical science; and the philosophy which each reader may have already made for himself may be impervious to this or that deduction which Miss Young draws from her fundamental idea. To the present reviewer, for example, the chapters on time and space appear the least satisfactory, while that on good and evil is one of the most satisfactory. To others the appeal will be different. But the work that has been done and the book that has been written are worth while. The style is so smooth and the use of metaphor so frequent and so apt, if the limitations of its logical use are constantly borne in mind, that it is easy to be carried along interestingly from paragraph to paragraph and yet to miss at times the flow of the argument as a whole. If opportunity occurs, as it should, the author might be well advised to break up her chapters into sections, with headings indicating the successive steps of the discussion; and it is possible that a synopsis of each chapter inserted at some appropriate place, in the table of contents or elsewhere, would be helpful.

NOTES ON BOOKS

In *A Textbook of Laboratory Diagnosis*[4] Drs. E. E. OSGOOD and H. D. HASKINS present an outline of laboratory diagnosis on the lines taught in the medical school of the University of Oregon. An excellent feature of this book is the fact that care has been taken to associate the investigation of clinical symptoms with the employment of laboratory procedures. An index of diseases at the end enables quick reference to be made to any specific test in relation to a particular diagnosis, and, from the student's point of view, this should also be particularly valuable in the work of revision before an examination.

The little work on the Therapeutics of the Deadly Sins,[5] by Dr. J. LAUMONIER, which is based on lectures delivered by him in his capacity of honorary professor at the Paris École de Psychologie, has recently appeared in a revised and enlarged second edition. It consists of four chapters, devoted respectively to introductory remarks, and the three "deadly sins" of love of the table, idleness, and sensuality, with their appropriate treatment. Special emphasis is laid on the importance of the autonomic nervous system and the endocrine system, and the part which should be played by the medical practitioner in simultaneous application of psychotherapy and somatic treatment.

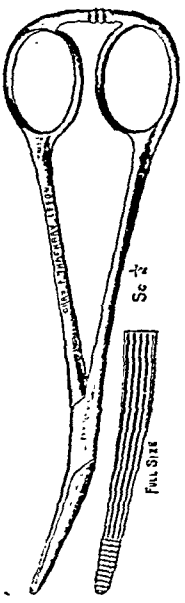
[5] *La Thérapeutique des péchés capitaux: Gourmandise, Paresse, Luxure.* Par Docteur J. Laumonier. Deuxième édition. Paris: Le Français. 1931. (Pp. 196. 15 fr.)

In his memoir on Malaria in Russia in relation to Soil and Climate,[6] which forms an epidemiological commentary on Dobreitzer's report on malaria in Soviet Russia, Dr. FRIEDRICH WOLTER adopts the following principles agreed upon by the malaria conferences held at Geneva in 1928. (1) In the present state of science the aim of measures for combating malaria should merely be to check it as far as possible as an epidemic disease. Any measures which claim to do more, such as its complete extirpation, can only be justified under special circumstances. (2) It is not always necessary to control malaria by a method resting on the knowledge of its transmission by mosquitos. (3) In every country the measures taken for controlling the disease must be preceded by investigations for determining which method is most suitable for the local conditions. (4) At the present time no one method is to be preferred to all the others in the prophylaxis of malaria. Wolter, who is an adherent of the Sydenham-Pettenkofer conception of epidemiology, is in favour of considering the extraordinary increase of malaria in Russia in 1923 as due to telluric and climatic conditions, and he regards a change in agrarian policy and sanitation of the soil as essential, because in the absence of such a course all other measures are doomed to failure.

Messrs. H. K. Lewis (136, Gower Street, W.C.1) have issued a supplement (1928–30) to the catalogue of their medical and scientific circulating library, of which a notice appeared in our issue of August 24th, 1929. This supplement is planned on the lines of its predecessors, and forms a useful summary of recent medical literature. The price is 2s. net, or 1s. to subscribers.



Reprints of a large number of contributions to medical science have been collected, within paper covers, as *Researches Published from the Wards and Laboratories of the London Hospital during 1930*, and are published by Messrs. H. K. Lewis and Co., Ltd., at 7s. 6d. the volume.

PREPARATIONS AND APPLIANCES

AN IMPROVED ARTERY FORCEPS

Mr. HAROLD DODD (London, W.) writes: The average artery forceps frequently has the following disadvantages. (1) It is usually straight, and so will not clip "round a corner." (2) The jaws are transversely serrated, and when a little worn will not surely grip a ligature (as when tying a "no touch" knot); also when applied to a width of appendicular mesentery, omentum, broad ligament, or hernial sac, they frequently allow the tissue held by the middle of the jaws to slip out, and time is consumed in correcting the error. (3) The handles lend themselves readily to entangling loops of suture material and other artery forceps then in use, either round the neck of the rings or between the rings. The Glendenning ratchet only partially overcomes this.

I have attempted, in the forceps here illustrated, to overcome these objections. They are of robust, but not heavy, construction; box-jointed, well balanced, with large, thin, easily accessible handle rings, and a stout end-placed ratchet; this latter adds power to the jaws and elasticity or "whip" to the handles, permitting easy release by the left hand. The jaws are medium-pointed and angled. The serrations are transverse at the tips and deeply longitudinal in the remainder of their length; this successfully holds ligatures, omentum, etc. The streamlined handles and Glendenning ratchets are effective in preventing loops of suture and other instruments from becoming entangled. I have used them for two and a half years.

I am much indebted to Messrs. Chas. Thackray of Leeds, who have ably made (in several sizes) the progressive patterns leading up to the model here illustrated.

British Medical Journal

SATURDAY, AUGUST 22nd, 1931

CHILDREN AT THE SEASIDE

It may well be the instinct of the islander, penned in cities, that impels him to take advantage of the new facilities of transport to the seaside. In any case, a centrifugal movement of population to the coast during the summer months is an outstanding fact in these days, an exodus which on a single Bank Holiday, by railway alone, is reckoned in millions. The same tale is told by the recent multiplication and growth of seaside resorts. Figures supplied from many of these places show that the extent of popular bathing, especially by children, is unprecedented. The question is a pertinent one: how are these children from the cities affected by the sea climate and by daily immersion in the sea?

In countries with a considerable seaboard medical men are taking an increasing interest in marine health resorts: witness the formation in 1914 of the International Congress of Thalassotherapy and its recent well-attended meetings in Italy, Rumania, and France. In Germany there are associations of medical practitioners on the Baltic and the North Sea, and in Belgium a new international journal, *La Cure Marine*, has appeared in the present year. All these organizations have for their object the precise study of the effect of marine climates and bathing on health at all periods of life. Like some branches of physical medicine, it needs to be reclaimed from irrational empiricism. Dr. Ceresole in Italy, among others, has pointed the way to a much-needed physio-pathological study of thalassotherapy.

It is often difficult, at home, to draw a clear line between normal and defective health, but a holiday at the seaside, with its abrupt change of climate and exposure to cold in bathing, often furnishes the test by which abnormal conditions of health may be detected. It is, to some extent, a therapeutic classification for delicate children. Normal school children and jaded but healthy adults can always, and immediately, find at the sea the complete change of scene, with the tonic influences of light, air, and water, which are all that they need for a summer health holiday. But this is not at all the case with perhaps the equal number of persons in subnormal health who are to be found at the seaside; such are the catarrhal, nervous, and chilly children, who perhaps are never ill and never well, but in whom a low and sensitive condition is a standing menace, and invites a variety of infections. For them the strong prescription of the sea must obviously be applied with care. The use of sea climates and bathing for delicate children presupposes in the first place a selection and differentiation of cases referred to the coast, whether it be to the marine hospital, the convalescent home, or the holiday centre. It also presupposes observation after arrival, and especially the regulation of exercise, rest, degree of exposure to sun, air, or sea, according to the reactions produced; and lastly, proper measurements and records. Children tolerate so much that it may not be recognized that they react in the most varied ways to physical influences. The marine climate, and especially bathing in the open sea, with its low temperature and risk of shock enormously increase the cooling of the body and make a heavy demand upon heat production, metabolism, and nervous energy, and where these powers are defective may evoke unfavourable reactions, which time, patience, and a course of re-education could easily have averted.

It is on account of the frequent and gratuitous ill-effects—chills, catarrhs, gastro-intestinal disturbances, rheumatism, heart symptoms, nervous disturbances, febrile "sur-saturation"—that some seaside practitioners in different countries have expressed grave doubts whether, on the whole, sea-bathing for children is not more injurious than beneficial. They have been painfully impressed by its too prevalent abuses: the unwilling with the willing prematurely hurried into the water, without acclimatization, and perhaps immediately after a meal; the bathing in all weathers, too frequently repeated, and much too prolonged; the endless wading on the shore; and the spectacle of children blue with cold and shivering in the wind from excessive and uncompensated exposure. These questions have been under discussion by the new Section of Hydrology and Climatology at the British Medical Association's Annual Meeting at Eastbourne. It is evident from reports from the British coasts that medical officers of health and practitioners, as well as local authorities, are not unaware of the dangers to which delicate children are exposed. At the more progressive seaside resorts efforts have been recently made to guard against them. Some, like Hastings, have published rules and hints for bathers. Others, like Margate, have set up excellent shelters on the beach and provide hot drinks and hot foot-baths after the bathe, which are a great assistance to favourable reaction. In many places hot sea-baths, as at Eastbourne, have been installed for the use of those for whom cold open-air bathing is injurious; and these, as well as the marine climate, have been reported upon as beneficial for convalescents and others, including rheumatic subjects, who are, temporarily perhaps, in a low and exhausted condition of health. Another provision of special value for delicate children is the sheltered, comparatively shallow, swimming pool of fresh sea water, as at Lowestoft, Hunstanton, and Southport. In sunny weather the warmth and shelter of these pools make the water possible and pleasant for chilly subjects, and an effective means for the gradual re-education to cold.

Tuberculous children are now treated in many countries with striking success on the coast, and the needs of non-tuberculous children are too little considered. In addition to the catarrhal, the nervous, and the rheumatic, very many children are subnormal in nutrition and development, in peripheral circulation, in resistance to cold. These common conditions,

with non-pulmonary tuberculosis, are amenable to physical treatment at the seaside. Dr. Carl Häberlin, whose opening paper we publish this week, gives a summary of his work for non-tuberculous children at Wyk, on the further side of the North Sea, where he directs a hospital of 300 beds, with various convalescent homes. He describes the methods and technique which belong to the marine hospital, especially the tests by which the reactions of children under treatment can be measured, and the results of treatment graphically recorded. In another place he has set forth the organization by which children from Berlin and Hamburg are selected by medical officers of friendly societies, schools, and hospitals, and the Ministry of Health, and distributed to appropriate town clinics, marine hospitals, or homes and holiday colonies, and has also described the system of subsequent after-care.

We are glad to hear that there is some prospect of an effective organization of medical men interested in the problems of thalassotherapy in this country. The 6,000 miles of seashore of the British Islands, with their temperate and invigorating climates, have a great variety of air and shelter, at different seasons, on the North Sea, on the Atlantic, and on the long range of the South Coast. Such a provision of nature is unrivalled in Europe, and suggests large possibilities for the health of a crowded industrial population. It is possible that, especially for the children from towns and cities, something like a national preventive and curative regime might be made available at the seaside, under medical men of special experience and training.

YELLOW FEVER

The incidence of yellow fever during the past four years is the subject of a report by the Health Section of the League of Nations.[1] Study of this document shows that during the period under review there has been a gradual disappearance of the disease in West Africa, or at least of its manifestations among Europeans, while in contrast there has been a marked increase in its prevalence in South America. The reappearance of cases in that part of the world is very disquieting, for as a result of intensive campaigns, directed mainly against the yellow fever mosquito, and generously supported by the Rockefeller Foundation, there were some grounds for believing that the disease had been eradicated from the New World, as two years had elapsed without a single case having been recorded. Unfortunately the disease again broke out in Brazil during 1926, and in 1928 and 1929 there was a serious epidemic in Rio de Janeiro, where no cases had been recorded during the preceding twenty years. The toll of this epidemic in 1929 in the city of Rio was 613 cases with 362 deaths, and doubtless many unrecognized cases were present. During the same year it also reappeared in Colombia. In 1930 the disease abated in Brazil, but during the first quarter of the present year 34 cases have been recorded from thirteen different and widely scattered localities. The lack of connexion between these cases strongly suggests that yellow fever may persist in a country without being revealed by epidemic outbreaks, and this view is supported by the results of immunity tests of the blood of natives in Nigeria, referred to in our leading article of December 20th, 1930. Similar "protection" tests, made by injecting monkeys with serum from the individual to be examined, and then with a lethal dose of yellow fever virus, have been applied in Bahia. Out of 144 persons tested in this manner no fewer than 44 gave complete protection, which suggests that rather more than 30 per cent. of the population must have been previously infected. Such figures, though giving only a rough approximation to the truth, are so enormously in excess of the number of recorded cases that in both West Africa and South America it is evident that the disease must persist in the native population under a more or less latent form, and in such localities the disease can reappear in epidemic form when the proportion of non-immune individuals, or the index of the transmitting mosquito, is sufficiently high.

The recent development of commercial air services has created a new sanitary problem, for *Aedes aegypti* (=*Stegomyia fasciata*) is very widely distributed, and the importation of yellow fever into the East, in many parts of which this mosquito abounds, might have disastrous consequences. It is open to question, however, whether the consequences would be quite so catastrophic as those suggested by recent statements, which have been the subject of exaggerated comments in the lay press, for it is by no means certain that this disease could become established in the East. There is some evidence to show that an attack of dengue confers immunity against yellow fever, for Dinger, Schüffner, Snijders, and Swellengrebel[2] found that when monkeys which had recovered from experimental infection with dengue were inoculated later with a virulent strain of yellow fever no fewer than eight out of eleven were resistant, though the mortality of this strain in normal monkeys exceeded 90 per cent. These results—combined with the fact that, though having the same transmitting host, the two diseases never occur together in the same locality—suggest that there may be other explanations besides climate barriers for the restricted distribution of yellow fever. Nevertheless, no one will question the importance of taking every possible precaution to prevent the introduction of the disease to such localities as East Africa and the Orient. In this connexion the Advisory Council of the League of Nations Eastern Bureau at Singapore in 1930 has emphatically urged stringent measures, more particularly (1) legal decrees forbidding anyone to import or keep yellow fever virus for any purpose whatever in Eastern countries open to contamination; and (2) the interdiction of air traffic between contaminated or suspected

areas and the Eastern countries until all the measures recommended by the Office International d'Hygiene Publique have been effectively applied. We may note that the Governments of British India, Malaya, Australia, and the Philippines have already forbidden the introduction of the virus even for experimental purposes. It is justly pointed out that there is sufficient opportunity for the study of yellow fever in the scientific institutes of countries free from *Aedes*, without jeopardizing the population of countries where this mosquito is present.

THE "LANCET" COMMISSION ON NURSING

The impression that the present state of the nursing profession in Great Britain is unsatisfactory is substantially borne out by the second interim report of the *Lancet* commission on nursing,[1] which was published on August 15th. The report is essentially a statement of ascertainable facts relating to the professional standards, training, life, amenities, and remuneration of those engaged in caring for the sick. Later in the year the commission intends to present its final report, in which it will suggest remedies to meet the various problems that have been brought to light as a result of the replies from 686 hospitals to its recent questionary. Any expression of opinion on what these remedies should be is better withheld until the final verdict of the commission is known. In the meanwhile, all those interested in this important question will do well to study in detail this statistical analysis, bearing in mind—may we suggest—that nursing is a profession whose difficulties have increased to such an extent with the advancement of medical science, and which demands such a combination of qualities in those engaged in its practice, that its professional status must be determined and its constitution reorganized if existing disabilities are to be remedied. Is there a shortage of hospital nurses? The figures, taken by themselves, do not indicate any serious deficiency. The 686 hospitals have a nursing staff of nearly 44,000, and the deficiency of staff as compared with full establishment works out at 125 sisters, 403 nurses, and 802 probationers. The hospitals have been divided into four types—namely, those approved as schools for complete training, for partial training, for special training, and those not approved. In the London voluntary hospitals approved as complete training schools the deficiency of staff nurses is 2½ per cent.; it is 5 per cent. in the provincial voluntary hospitals similarly approved, and 13 per cent. in the approved London and provincial municipal hospitals. The probationers are within 1 per cent. of establishment in the London voluntary hospitals, and only in the fever hospitals are they as much as 10 per cent. below. The question was put: "Do your advertisements for sisters, staff nurses, and probationers usually bring sufficient replies from suitable candidates?" The deduction drawn in the report is that, taking the hospitals as a whole, "roughly one-fifth of them fail to secure suitable candidates as sisters, and one-half of them fail to secure the staff nurses and probationers of the standard that they require." Another striking fact is the annual wastage of probationers. In 363 hospitals giving information on the point, half the probationer staff is replaced every year, whereas with a three or four years' course of training the normal replacement would be one-third or one-fourth. This may be because some hospitals recruit women who are never likely to prove efficient nurses: one institution even states that it engages all who apply, and weeds them out afterwards. The statistics collected by the commission do not reveal much with regard to the conditions of service which was not in a general way already known. The age of entrance is seldom below 18; very few London voluntary hospitals take probationers younger than 19. For service in most of the voluntary hospitals education at a secondary school is necessary; the municipal hospitals are more often content with a different [illegible]enth standard of the elementary school. In other [illegible]n voluntary hospitals there are fewer than [illegible] occupied beds to each member of the nursing staff, and the same is true of 96 per cent. of the provincial hospitals. The municipal hospitals work on a definitely higher ratio of beds to staff, and the rates of pay are higher than in the voluntary hospitals. In few of the latter is the pay more than £20 in the first year, with board and lodging, uniform, and laundry provided. Three-fourths of the municipal hospitals pay £30 per annum or more. Staff nurses are paid from £50 to £65, and sisters from £70 to £85 a year, here again with some tendency for municipal hospitals to pay at a rather higher rate. The day's duty in most hospitals is from 12½ to 13¼ hours, and the night duty 11½ to 12¼ hours. Annual leave for the probationer is usually three weeks, the London voluntary hospitals being specially generous in this respect. Half the hospitals allow a weekly half-day holiday, and nearly half allow a whole day, while most hospitals allow at least two hours' off-time daily. But a complaint frequently made is that the nurse does not know her free hours beforehand. Altogether the nurse may be said to have a sixty-hour week, as compared with the forty-hour week of women in other employment. How far this factor—together with the restrictions of institutional life—deters the freedom-loving young woman from taking up a nursing career cannot be estimated. Some argue that the living-in system prejudices recruiting; others that a living-out system would be fatal to the profession. Some complain of long hours and low pay; others say that these would not be objections if prospects after qualification were improved. In the experience of certain hospitals the shortage has disappeared when hours were lowered and pay increased; others found that these changes resulted in no improvement, or only attracted the wrong type of girl. Evidently there is room for some alteration in the training system. It is suggested that preliminary training schools should be instituted where, by a system of co-operation between the hospitals and the education authorities, the girls could receive theoretical instruction for some months before entering the ward, as it is thought that the combination of ward work and theoretical work at the beginning may impose too great a strain. The final report of the Earl of Crawford and Balcarres and his colleagues of the commission, embodying their opinions and recommendations, is expected before the end of the year.

[1] The *Lancet* Commission on Nursing. Second Interim Report. With Statistical Analysis of the Questionnaire issued to Hospitals by the Commission. By A. Bradford Hill, Ph.D., D.Sc. Supplement to the *Lancet*, August 15th, 1931. (6d.)

THE RESULTS OF B.C.G. VACCINATION IN FRANCE

The Institut Pasteur of Paris has published the results of a second inquiry into the effect of prophylactic vaccination with B.C.G. in France.[1] The figures that are now presented refer to 8,075 infants born or brought up in a tuberculous environment and vaccinated with B.C.G. some time between July, 1924, and December 31st, 1929. These infants were kept under observation by dispensaries, which furnished the figures relating to them. The inquiry was made on June 1st, 1931, when every vaccinated child that survived must have been at least 1 year old, and when some children must have been over 6 years old. Of the 8,075 infants, controlled by 114 dispensaries, 89 died before the age of 1 month. Of 2,685 infants aged between 1 month and 1 year, 371 died; of 4,811 children aged from 1 to 4 years, 121 died; and of 579 children vaccinated more than four years previously, none died. These figures, which refer to deaths from all causes, show that the mortality in vaccinated infants aged 1 month to 1 year was 4.6 per cent., and from 1 to 4 years 1.5 per cent. The first figure is compared with the general mortality in non-vaccinated infants (whether brought up in a tuberculous household or not), which is stated to be 6.10 per cent., and with the general mortality in non-vaccinated infants brought up in a tuberculous environment, which is stated to be 16 to 25 per cent. On the basis of these figures it is concluded that the general mortality in vaccinated is less than that in unvaccinated infants. Admitting these figures to be exact, one is faced with their interpretation. It has already been shown by a very careful inquiry in Lancashire by Dr. Lissant Cox[2] that the general mortality in infants aged 0 to 1 year brought up in tuberculous households may be less than that for all infants in the county. The mere demonstration, therefore, of a lower general mortality among the vaccinated than among the unvaccinated group of French infants does not necessarily mean that the vaccine played any part in the determination of this difference. So far as the figure of 16 to 25 per cent. mortality among unvaccinated children brought up in a tuberculous environment is concerned, this is an estimate which, as Professor Greenwood[3] has already pointed out, entirely fails to agree with the carefully collected data of other workers. It is difficult to understand why Professor Calmette now lays so much stress on the lowering of the general, as opposed to the tuberculosis, mortality in vaccinated infants. If his observations are correct there seem to be three possible explanations: (1) the groups of vaccinated and unvaccinated infants are not strictly comparable, the former being favoured in some way so as to run less risk of dying; (2) the vaccine is entirely non-specific, in which case it would surely be wiser to use some form of protein to which less exception could be taken; and (3) a considerable number of diseases which prove fatal to infants during their first year of life are in fact due to tuberculous infection—a possibility which at the moment is unsupported by any real evidence. Unless Professor Calmette can prove the truth of this last explanation, it seems that either the first or the second must be correct, in which case prophylactic vaccination with B.C.G. will cease to be of further interest to scientific medicine. Professor Calmette expresses the hope, which he fears to be a vain one, that he may succeed in convincing his prejudiced antagonists. Not only will he fail in this, but if he can bring forward no stronger evidence than is now presented he will fail to convince even those who are perfectly ready to be convinced, and who are waiting only for facts in place of unsupported or obscure assertions.

IRRADIATED ERGOSTEROL AND PARATHYROIDS

The general result of biochemical research during recent years has been to emphasize the complexity of the conditions regulating calcium metabolism. This has been shown to be influenced chiefly by the calcium-phosphate intake, by the vitamin D supply, and by the parathyroid secretion. The interrelation of these various factors has, however, remained extremely obscure. Extensive researches recently published[1] by Taylor and others of the University of Toronto have thrown considerable light on this elusive problem. In the first place, these workers have shown that the toxic effects produced by excess of irradiated ergosterol are identical with those produced by excess of parathormone. This parallel holds good both for the symptoms and for the pathological changes produced by intoxication with these two products, and also for the details of the changes observed in the blood chemistry. Furthermore, they find a remarkable parallel of the specific variation in susceptibility to these two substances. For example, the curative dose per unit of bodyweight of vitamin D is approximately the same in rats and dogs, but the lethal dose per unit of bodyweight of irradiated ergosterol is about five hundred times greater in the rat than in the dog. Moreover, the dog can easily be killed by excess of parathormone, whereas the resistance of the rat to this hormone is too high to permit determination of the toxic dose. In general, those species which show a high resistance to the toxic action of irradiated ergosterol are tolerant in a corresponding degree to the action of parathormone. The authors conclude that there is probably a direct relation between the action of the two substances, and that the sterol acts by stimulating the parathyroid tissue. They show that there are two possible sources of error in the evidence derived from parathyroidectomy. In the first place, it is very difficult to be certain what proportion of the total parathyroid tissue in the body has been removed by operation, and, in the second place, the remarkable specific differences in susceptibility to irradiated ergosterol and parathormone make it very difficult to correlate the effects observed when they are tested on different species of animals. The authors state that therapeutic doses of these substances tend to favour the passage of calcium from the blood into the bones, and may thus cause a fall in serum calcium, though the increased absorption brings about a positive calcium balance. Toxic doses of these products cause a passage of calcium from the bones into the blood, a rise in blood calcium, and a great increase in the calcium excreted by the kidneys. This difference between the therapeutic and toxic actions of parathormone and irradiated ergosterol has been a

[1] Taylor, Weld, Bramon, and Kay: *Canadian Med. Assoc. Journ.*, 1931, xxiv, 763; xxv, 20.

fruitful source of confusion in the past. The general result of these researches is to give a much clearer and simpler picture of the relation between the factors determining calcium metabolism. From the point of view of practical therapeutics, the most important point in the paper is the demonstration of the remarkable variations shown by different species of animals in their resistance to excess of irradiated ergosterol. The fact that excess of this drug could produce toxic effects naturally caused alarm when it was first discovered, but this alarm was relieved when it was shown that the toxic dose was many thousand times greater than the curative dose. This last result was, however, obtained on rats, and Taylor and his co-workers have shown that it is not true in the case of dogs. They found that death of adult dogs followed the administration of irradiated ergosterol when the amount given had a greater potency than twenty times that of the maximum therapeutic dose. Moreover, puppies showed a greater susceptibility to overdosage than did full-grown animals. The authors point out that since the dog and the human are, as contrasted with other species, highly susceptible to parathormone, it is quite likely that the human subject may share with the dog a high susceptibility to irradiated ergosterol. They cite clinical observations as direct evidence for this view. It is scarcely necessary to point out that this conclusion is of grave importance, and it is to be hoped that further investigations will be made on this subject.

PATERSON OF HEBRON

Dr. Ewing's sympathetic biography of his remarkable friend, *Paterson of Hebron*,[1] is one of the best accounts of pioneer medical missionary service that has appeared in recent years. The main facts of Paterson's life are fairly well known. He was born in Madras with a true sense of the East in his blood, and his strong emotional nature carried him naturally into the tradition of his father's work. Educated at Edinburgh, he showed his quality first in Bethnal Green, then in Aden, having rapidly assimilated at Cairo some learning of Eastern life and languages. In 1893 he accepted the post of medical missionary at Hebron, the isolated and dangerous hill city of Abraham's sepulchre, one of the four sacred towns of Islam. There Paterson established a dispensary, and for thirty years laboured with unremitting zeal for the welfare of a large and widely scattered population. Circumstances at first could hardly have been more unfavourable ; but the success with which he raised his hospital for the sick won the confidence and admiration of Jew and Bedouin alike. During the war Paterson served with Scottish units and in the Egyptian Expeditionary Force, but on the liberation of Palestine he returned immediately to Hebron, where he was appointed principal medical officer of the district. With incessant energy, but with failing funds, he worked at the restoration of his hospital, which in his absence had been rifled by the Turks. It seemed a unique opportunity for the Church of Scotland, but its advisory committee declined to continue its support. We cannot comment here on the judgement of the visiting commission, sent out in 1920, that the work at Hebron had not sufficient missionary value, but it is a curious fact that none of its members appear to have had any medical qualification for investigating the conditions of a medical mission. In spite of his Church's criticism, however, Paterson's record will endure, not only as a historical document, but as a testimony to the living faith of a chivalrous physician.

HOW TO PREPARE A PEDIGREE

We commend to the attention of our readers a little booklet published by the Eugenics Society on how to prepare a family pedigree. A brief survey of the literature on any inherited condition will reveal the fact that in the preparation of pedigrees unorthodox and obscure symbolism is often employed, that errors are probably present, and that, above all, vital information is omitted. It is usually the case that any attempt to define the mode of inheritance of a condition must depend upon the simultaneous analysis of a large number of records accumulated by a number of different investigators. Faulty and incomplete records make this task a difficult one, and conclusions may be dubious instead of being clear-cut, or they may even be erroneous. Those who prepare pedigrees should particularly notice that their work will certainly be utilized in this way by others, and that often their results will be used many years after they have been published. The necessity for very full information, therefore, may not be particularly obvious at the time of publication of a paper, but such information may become of great value at a later date in the light of subsequent discoveries. Pedigrees published a century ago may be as useful, if they are complete, as those published during the present year. It is unfortunately the case that in the matter of faulty pedigrees medical writers are much to blame. The Eugenics Society has performed a good service in producing this pamphlet. Detailed directions are given in a simple and compact form for preparing a chart, with the use of a symbolism that for the most part is universally accepted. The booklet contains, in addition, a sheet of squared paper on which the pedigree is recorded and a number of blank sheets for supplementary notes. It is intended that the medical man or geneticist should hand the booklets to intelligent patients, who would be well able to prepare the pedigrees themselves after reading the instructions. We think it possible that many English students of the subject would prefer to use the conventional male and female signs instead of squares and circles, but the point is more a matter of taste than anything else, and the benefits of uniformity are so great that this small sacrifice might well be made. It is also a little doubtful whether it is necessary to include special symbols for carriers of a condition. In contradistinction to the rest of the information symbolized, this is a matter of inference and not a simple record of observed fact. These are small points, however, and it is to be hoped that the efforts of the Eugenics Society will be crowned with success, and that the result will be a general improvement in the standard of published pedigrees.

We regret to announce the death of Group Captain Martin Flack on August 16th. We hope to publish an obituary notice in next week's *Journal*.

ENDOCRINE PHYSIOLOGY

SIR E SHARPEY SCHAFER'S PURSER LECTURE

The following is an abstract of the John Miller Purser Lecture, delivered in Trinity College, Dublin on June 26th, by Sir Edward Sharpey Schafer, Sc D, F R S, professor of physiology in the University of Edinburgh

After briefly alluding to the career of the eminent physiologist in whose honour the lecture was instituted, the lecturer proceeded to state that physiology must be looked upon as having begun with Harvey's discovery of the circulation of the blood The recognition of the regulation of bodily functions by the nervous system constituted the next advance, and occurred about a hundred years ago A new physiology, which did not supersede the old, but which assimilated and was incorporated with it had sprung up within the last fifty years The old physiology had been based on nervous regulation, while the new physiology was based on chemical regulation We had learned to recognize that the functions of the organs were not governed solely by nerves, but were influenced by chemical substances in the blood, the nerves and nerve centres being themselves subject to chemical influences On the other hand, chemical regulation might itself be influenced by the nervous system, so that the reaction was mutual The action of these chemical substances was often spoken of as "humoral," because they were conveyed in the blood or lymph Some of them, however, were actually produced *in situ* in the tissues upon which they acted, and in such cases their action, though chemical, would be incorrectly described as humoral

The first indication that the regulation of function might be effected by chemical rather than by nervous agencies was pointed out by Berthold in 1849 He found that the implantation of testicular grafts into castrated cocks would restore the appearance of the birds to that of normal cocks, and concluded that the testicles must pass some substance into the blood which reacted on the organism in general Later, in 1883 the Swiss surgeons J L and A Reverdin and Thomas Kocher had described a cachexia, which Kocher termed "cachexia strumipriva," following extirpation of the thyroid gland They compared it with the conditions which accompany atrophy of the gland in children or its degeneration in the adult—namely, cretinism and myxoedema That myxoedema was due to the absence of an internal secretion of the thyroid was shown by the fact that the symptoms were removed by the administration of thyroid extract, or of thyroxine, the chief ingredient, now synthetically prepared

In 1855, before these facts relating to the thyroid had been discovered, Thomas Addison had described the disease which bears his name, and had associated the symptoms with destruction of the suprarenal capsules Following the publication of Addison's memoir Brown Sequard and others had carried out experiments showing that complete removal of both suprarenals in animals was invariably fatal, although the pigmentation characteristic of Addison's disease in man was never observed in animals Nearly forty years more elapsed before it was discovered that a physiologically active material was produced in the medulla of the suprarenal capsules and they were recognized as organs of internal secretion Adrenaline was the first of the active principles of the internal secretions to be isolated and synthetized

Thyroxine and adrenaline might be taken as yielding examples of different actions produced by internal secretions Adrenaline produced immediate effects on heart, blood vessels, liver, salivary glands, intestine, pupil, and spleen but the effects soon passed off owing to the destruction of the secretion either in the tissues or the blood, thyroxine, on the other hand, acted slowly and gradually, influencing nutrition, stimulating cell multiplication and producing characteristic effects on the general metabolism The two substances also differed in their mode of secretion Adrenaline was passed from the cells of the suprarenal medulla directly into the blood The blood in the medulla was not contained, as in most organs, in capillary vessels from which the plasma or lymph escaped to bathe the tissues, but flowed in sinus like channels between the cells, so that it was in direct contact with the cells without the intervention of lymph In the thyroid the blood was conducted in ordinary capillaries, and the secretion passed from the vesicles into the lymph of the interstitial spaces, and thence into the efferent lymphatics and eventually into the blood by the great lymphatic trunks

On consideration of the organs and parts of organs credited with the production of an internal secretion, it was found that those containing sinusoids, into the blood of which the secretion was directly passed, were the suprarenal medulla, the liver, the islets of Langerhans of the pancreas, the pars anterior of the pituitary body, perhaps also the pars tuberalis, the parathyroids, the corpora lutea, and the placenta Those which possessed ordinary capillaries and passed their secretions into the lymph were the thyroid, the suprarenal cortex, the pars intermedia, and the pars nervosa of the pituitary, and the gonads The distinction was that in one case the secretion was passed directly into the blood and produced its effects immediately, and in the other its passage into the blood was slower and its effects were produced more gradually The inference might be drawn that in the case of secretion directly into the blood the supply was varying momentarily, according to the immediate calls of the organism, and that when the secretion reached the blood through the lymph its purpose was concerned with gradual changes affecting growth and nutrition

The internal secretions of some endocrine organs were independent of the nervous system, and influenced directly by constituents of the blood With others, secretion was governed by the nervous system It could be shown that the secretion of adrenaline by the suprarenal medulla was dependent on the integrity of the nerves passing to the organ Tournade had shown that the raising or lowering of the blood pressure in the aorta and the carotid sinus affected not only the vasomotor centre, but also the adrenaline secreting centre in the medulla, and this, by increasing or diminishing the amount of adrenaline poured into the blood, assisted the regulating action of the vasomotor centre When first the presence of so powerful a stimulant of vascular musculature was shown to be yielded by the suprarenal medulla it was conjectured that the purpose of the secretion must be to aid the nervous system in maintaining the blood pressure and the tone of the arteries. But attempts to demonstrate that there was a normal or physiological secretion of adrenaline into the blood had been unsuccessful until the experiments of Tournade, working for the most part with Chabrol, had set it beyond dispute

In these experiments two dogs were anaesthetized with chloralose from one (A) both suprarenals were removed, and from the other (B) one suprarenal usually, the right The whole of the blood coming from the remaining suprarenal of (B) was allowed to pass into (A) by anastomosing the suprarenal lumbar vein of (B) with the external jugular vein of (A), so that (A) received all the adrenaline secreted by (B) Anything affecting the adrenaline secretion of (B) would therefore show itself in the increase or diminution of blood pressure in (A) The following results had been obtained by the use of this method

1 If the venous connexion between the two dogs was interrupted by pinching no change occurred in (B) but the blood

pressure in (A) fell. On releasing the vessel, adrenaline effects were again immediately apparent in (A).

2. If the left splanchnic nerve of (B) was cut, the blood pressure fell in both dogs, in (B) owing to paralysis of the vasomotor nerves to the abdominal viscera, in (A) in consequence of the failure of the suprarenal of (B) to secrete adrenaline. On stimulation of the cut end of the splanchnic the blood pressure in (B) rose owing to contraction of the abdominal vessels; and after a short delay, due to the time taken by the adrenaline secreted in (B) to reach the circulation of (A), the blood pressure also rose in that animal.

3. If the vasomotor centre in the bulb of (B) was directly stimulated, there was an immediate rise in the blood pressure of (B), due to general vascular contraction, and delayed rise in the blood pressure of (A), due to increase of adrenaline. If the fourth ventricle of (B) was painted with cocaine, the activity of the adrenaline centre became depressed, less adrenaline was secreted by (B), and the blood pressure of (A) fell.

4. If the blood pressure of (B) was lowered—by the intravenous injection of duodenal extract or by some other method—the adrenaline centre became reflexly stimulated, and more adrenaline was passed into (A), so that the blood pressure of (A) rose. Conversely, any agency raising the blood pressure in (B), such as stimulation of a sensory nerve, was followed by a diminution in the secretion of adrenaline and a fall in the blood pressure of (A).

The experiments of Tournade on this subject were numerous, and proved conclusively that the secretion of adrenaline was as intimately dependent upon the nervous system as was the secretion of saliva.

Following the discoveries relating to the thyroid and suprarenal medulla had come the observation by Bayliss and Starling in 1907 that an extract of duodenal mucosa contains a substance which, when injected into the blood, stimulates the secretion of pancreatic juice. To this substance they gave the name of "secretin," and spoke of it as a "chemical messenger"; later, assuming that all such chemical messengers possess a stimulating function, Starling suggested for them the general term "hormone." More recent writers had extended this term to apply not only to substances which excite, but to substances which depress activity. But the resemblance between the action of internal secretions and that of drugs was very close, and should be incorporated in the nomenclature. The term "hormone" was derived from ὁρμάω, I excite; Sir Edward said that in 1913 he had suggested that substances having an inhibitory effect might be distinguished as "chalones" from χαλάω, I restrain. It was not unlikely that for every hormone there was an antagonistic chalone.

It was further desirable to have a designation which would include both hormones and chalones, and the most obvious quality which they had in common was their resemblance to drugs. A short expression for "drug-like" would be "acoid," from ἄκος, a drug, and to this might be added the prefix αὐτός, indicating that these substances were produced by the body itself. He therefore had suggested the term "autacoid" to denote all specific principles of internal secretions, whether hormones or chalones. Although in most cases an autacoid was either exclusively hormonic or chalonic, there were certain exceptions, of which adrenaline was one. Adrenaline was hormonic in its action on the circulatory system, but chalonic in its action on the muscular coat of the alimentary canal.

Externally secreting glands might be classed under three heads: first, those which are exclusively under the influence of nerves, such as the salivary glands; secondly, those which are entirely under the influence of chemical substances in the blood, such as the mammary glands and kidneys; and thirdly, those which are influenced both by chemical substances and by nerves, such as the pancreas and gastric glands. The same distinctions appeared to obtain with the endocrine glands. Many organs were known to possess the double function of producing external secretions and of secreting autacoids internally. The gonads and the pancreas furnished examples of this double function, and further examples had been recognized in the formation of secretin in the duodenum, the production in the liver of an autacoid which stimulated the haematopoietic organs, and similar duality of function in the stomach and kidneys.

The internally secreting organs frequently influenced one another. Removal of the thyroid, for example, caused enlargement of the whole pituitary; destruction of the pituitary in the young animal arrested the development of the thyroid. The thyroid by its secretion stimulated the suprarenal medulla, and the resulting increased secretion of adrenaline provoked the hepatic and other cells to discharge their glycogen into the blood as glucose. The hyperglycaemia produced stimulated the islet tissue of the pancreas to an increased secretion of insulin. Another striking example of the interaction of these glands was furnished by the influence of the pars anterior of the pituitary on the sex organs. For this purpose the pars anterior produced two hormones. One stimulated the ovaries and caused maturation of the Graafian follicles; these in their turn produced an autacoid, oestrin, or folliculin, which initiated changes in the uterus for reception of the ovum if fertilized. The second hormone produced by the anterior pituitary stimulated the production, in the corpora lutea, of another autacoid (lutein), which promoted further uterine changes for the fixation of the ovum. In addition, the corpora lutea yielded a chalone which prevented the action of folliculin and the further discharge of ova. These autacoids of the pituitary and the ovary could be detected in the blood, and were secreted in the urine. A few drops of the urine of a pregnant woman injected under the skin of an immature mouse caused the premature appearance of oestrus, and constituted the basis of the Aschheim-Zondek test for pregnancy. In addition to the use of thyroxine in myxoedema, of insulin in diabetes, and of liver or stomach extract in pernicious anaemia, this test furnished another striking example of the application of the new physiology to clinical medicine.

Another class of autacoids were not formed in organs of internal secretion and passed into the blood, but were produced in the tissue which they were designed to influence. These might be termed "tissue-autacoids" to distinguish them from circulating autacoids. Little was known of their nature or mode of activity, apart from information derived from experiments on the heart. In 1921 Loewi found that Ringer's solution which had been used for perfusing a frog's heart inhibited by the vagus would produce an inhibitory effect if used to perfuse the heart of a second frog. Evidently impulses descending the vagus had caused the formation of a "vagomimetic" autacoid. Similarly, when the sympathetic fibres to the heart were stimulated a sympatho-mimetic autacoid was produced, which seemed to be identical with adrenaline; being a stimulating autacoid it was a hormone, and antagonistic to the vagal chalone. It was possibly owing to the local production of these autacoids in the heart that the pressor and depressor effects of the sympathetic and vagal nerves were actually due, and their formation probably explained the continuance of vagal and sympathetic action which was always observed for an appreciable time after stimulation of the nerves was discontinued.

These observations on the heart recalled the work, in 1913, of Demoor, who found that, in the dog, extracts made from a submaxillary gland which had been caused to secrete actively by stimulation of the chorda tympani would, if injected into a second dog, produce active secretion from the submaxillary gland. The active substance

in this case might be saliva itself, for Guimaris, in 1930, had found that if saliva, or an alcohol extract of saliva, were injected into the artery supplying the sub maxillary gland of the dog, free secretion was provoked, even if the chorda tympani had been cut and allowed to degenerate Other observers had found that a substance resembling adrenaline in action was formed in plain muscular tissue as a result of stimulation of the sympathetic, and that extracts of kidney produced diuresis if injected into the blood Metabolic autacoids or metabolites might have a local action affecting either the tissues or their blood vessels

Another class of autacoids, not produced by excitation of nerves, but inherent in the tissue or appearing spontaneously in it, had been studied chiefly in the heart The tendency to automatic rhythm of a heart removed from the body had long been thought to be due to nerves and ganglia within its substance But it had been shown that spontaneous contractions of separated portions of the heart, whether derived from auricles or ventricles, depended on the presence of nodal tissue ; that was to say, the muscular tissue forming the nodes, the auriculo ventricular bundle, and the network of Purkinje Demoor and Rijlant found that if the left auricle, which was devoid of nodal tissue, was completely severed from the right, it soon ceased to beat spontaneously , it could be made to resume its spontaneous contractions, however, by the addition of an extract of nodal tissue from the heart of another animal Again, Rijlant had observed that excision of the sinus node caused the right auricle to beat with a slower rhythm , but if the node was reimplanted the original rate of contraction was restored, although the continuity of the nodal fibres with the rest of the heart remained severed, Demoor considered that the nodal tissue produced a substance which diffused into the cardiac tissue and provoked contraction, while Rijlant suggested that the reimplanted node set up electrical changes which started the contractions of the neighbouring muscle at the same rate as those of the node

Little was known about the elimination or deactivation of autacoids In some cases the autacoid might form an inactive compound with some product of metabolism, and this probably occurred with adrenaline , others, including those secreted by the anterior pituitary, the ovary, and the placenta, were eliminated by the urine , the action of others might be arrested by the secretion of an antagonistic autacoid

Recapitulation might serve to emphasize the part played by autacoids in the animal economy The pituitary produced in its anterior lobe a hormone stimulating growth and a chalone restraining growth , other autacoids secreted here acted on the thyroid, the ovary, and the testis, and influenced metabolism Autacoids from the posterior lobe stimulated the heart, blood vessels, uterus, alimentary tract, the secretion of urine and milk, the action of insulin, and expansion of melanophores Possibly the pars tuberalis produced a special autacoid, the purpose of which was to regulate hydration The thyroid produced thyroxine, and also an autacoid which inhibited the musculature of the blood vessels Another thyroid autacoid excited contraction of intestinal muscle, while others influenced the gonads, the pituitary, and the suprarenals The parathyroids secreted the parathymone of Collip, which regulated the calcium content of the blood The islet tissue of the pancreas produced insulin, and the pancreas also elaborated a chalone which caused dilatation of blood vessels The ovaries secreted folliculin and lutein, and the gonads in both sexes formed autacoids which were responsible for the secondary sex characters, and inhibited those of the opposite sex The placenta yielded at least three autacoids similar to some formed in the anterior pituitary and the ovary Autacoids produced in the liver, kidney, and stomach stimulated the haematopoietic organs, and others formed in the mucosa of the stomach and duodenum influenced the secretion of the pancreas, liver, and gastric glands The suprarenal medulla was responsible for the production of adrenaline, while the cortex formed one autacoid acting on the respiratory system and another which appeared to counteract the otherwise fatal results of complete decapsulation. Lastly, there were the tissue autacoids, of which the cardiac autacoids were examples , three of these were known, one being inherent in cardiac muscle and responsible for its automaticity, the other two being formed under the influence of the vagus and the sympathetic respectively

In conclusion, Sir Edward Sharpey Schafer emphasized that the doctrine of internal secretion formed a new departure, since it necessitated the explanation of physiological phenomena in terms of chemical as well as of nervous regulation

REHOUSING IN LONDON

Within a radius of fifteen miles of Charing Cross there have been erected since the war 294,255 new houses and flats, sufficient accommodation to rehouse the entire population of Glasgow, as well as of the whole of Dundee Two thirds of these new London dwellings have been put up as a result of private enterprise , the remainder have been provided by local authorities, and, to a small extent, by housing trusts and public utility societies. The London County Council has contributed 41,000 to the number, half of which are comprised in its great estate at Becontree, and 46,000 have been provided by the City Corporation, the metropolitan borough councils, and the outer London local authorities Last year the total number of houses and flats built was 50,183, easily the largest number in any year since the war, or, indeed, so far as records go, in any year before the war Four out of five of these, however, were provided by private enterprise , the number provided by the local authorities, which has been falling for some years, was the lowest since 1925 These figures relate to Greater London, which, according to the recent Census, has a population of 8,202,818 In the County of London, with a population of 4,396,821, the housing activity has naturally been much less marked Of approximately 300,000 houses built during the last eleven years only some 50,000 are situated within the confines of the county—an indication of the way in which Londoners have spread their dormitories beyond the 117 square miles governed from the County Hall To what extent has a decade of energetic housing activity relieved the evil of overcrowding? The preliminary Census report shows that the population of the County of London has decreased since 1921 by 87,702 but as the 1921 Census was taken in June, when many Londoners are absent on holiday, and that of 1931 was taken in April, it is estimated that the real decrease is larger, being as much as 127 000 The net increase in the number of houses during the same period has been about 41,000, which would provide accommodation, at the perhaps too liberal estimate of 4½ persons to a house, for 185,000 persons The housing accommodation in the county shows an improvement of 7 per cent compared with that which existed in 1921 In Greater London the Census reveals an increase of population of 722,617 though it is believed that the real increase is only 672,000 if allowance is again made for the season at which the two censuses were taken On the estimate of a net increase of 280,000 houses, accommodation has been

provided for about 1,260,000 persons, so that here the improvement in the relationship between population and housing, as compared with 1921, is about 8 per cent. While the amelioration which these figures represent is a great achievement, there are two qualifying factors of importance. The first is that although there has been a large increase in population in Greater London, there has been a much larger ratio of increase in the number of separate families. Families are smaller than formerly, but there are more of them, and this explains why it is that many cases of serious overcrowding, where tenants are unable to obtain decent accommodation, are still being brought to the attention of local authorities. The second factor is that the totals of new houses quoted above, impressive as they are—extending to about 350 compact miles of new streets—relate to all classes of houses, not to working-class houses only. Considerably less than half the total of new houses are occupied by artisans. Of course, the provision of other types of dwellings such as those purchasable leasehold for about £1,000, of which there is a large number in the suburbs, must ultimately ease the pressure on working-class accommodation. But the fact remains that two out of three houses have been provided by private enterprise, and almost invariably for sale, not rental, catering consequently only for about one-quarter of the population. This explains why it is that in spite of rows of new houses spreading like scarlet-runners along the highways and byways of Middlesex, Essex, Kent, and Surrey, the pressure on working-class accommodation in London continues.

MEDICAL CONGRESSES, 1931

The following congresses and conferences on medical and allied subjects have been announced for the remainder of the year. Particulars are given below in the following order: date, name of organizing body, place of meeting, name of person to whom inquiries should be addressed. More detailed information about these meetings is given from time to time, as it becomes available, in the news columns of the *British Medical Journal*.

August 31–September 6. — International Congress of Neurology. Berne.

September 2–19.—International Illumination Congress. Great Britain. Colonel C. H. Silvester Evans, c.o. The Illuminating Engineering Society, 32, Victoria Street, S.W.1.

September 12–17.—International Congress of Tropical Medicine. Amsterdam.

September 13–19.—International Congress of Balneology. Carlsbad. Dr. Edgar Ganz, Carlsbad, Czechoslovakia.

September 14–16.—German Orthopaedic Society. Berlin. Professor Wollenberg, Prager Platz 5, Berlin-Wilmersdorf.

September 14–17.—American Public Health Association. Montreal. Secretary of Association, 450, Seventh Avenue, New York.

September 14–19.—Medical Association of South Africa (British Medical Association). Johannesburg. Dr. B. G. Melle, Medical School, Hospital Street, Johannesburg.

September 21.—Royal Institution (Faraday Centenary). London. Secretary of Royal Institution, 21, Albemarle Street, W.1.

September 21–23.—German Pharmaceutical Society. Vienna.

September 21–23.—German Association for Occupational Hygiene. Nuremburg. Secretary of Association, Platz der Republik, 49, Frankfort.

September 23–25.—Society for the Study of Metabolism and Diseases of Digestion. Vienna. Professor von den Velden, Bambergerstrasse 49, Berlin, W.30.

September 23–30.—British Association's Centenary Meeting. London. Secretary of Association, Burlington House, Piccadilly, W.1.

September.—Pan-Russian Congress of Gynaecologists and Obstetricians. Moscow.

October 1–3.—German Society for Urology. Vienna.

October 14–18.—International Congress of Comparative Pathology. Paris. Dr. Grollet, 7, Rue Gustave Nadaud, Paris, XXVIe.

England and Wales

The Royal Veterinary College

In view of the fact that the Popular Lecture at the Annual Meeting at Eastbourne was delivered by Professor F. T. G. Hobday, principal and dean of the Royal Veterinary College, the annual report for 1930 of this institution, which was published in the *Journal of the Royal Agricultural Society of England* (vol. xci) has special interest. The satisfactory position in England last year as regards foot-and-mouth disease is illustrated by a comparative table showing its monthly incidence in France, Germany, Holland, and Belgium. A total of eight outbreaks in England in 1930 contrasts sharply with over 36,000 in Germany and 7,000 in France. Professor Hobday calls attention to the gratifying result of the British method of stamping out this disease by using the special immunizing serum to protect contact animals. Progress in carrying out the provisions of the Tuberculosis Order of 1925 is considered by Professor Hobday to be less satisfactory, since on many occasions the notified tuberculous animals have been in contact with healthy animals long enough to have spread the disease. Much more remains to be done, apparently, in connexion with the separation of suspected cases, and in compensating farmers and dairymen for the extra expense and trouble incurred. Professor Hobday adds that the present is not a propitious time to increase the burdens of agriculturists and stock owners. Experimental work with two different kinds of preventive serums is being conducted in Norfolk and Cambridge. Outbreaks of sheep scab diminished markedly as compared with the five previous years, and for this improvement the action taken by the Veterinary Committee of the Royal Agricultural Society in 1929 can legitimately claim credit, especially for its press propaganda. A few isolated cases of anthrax in man were reported during the year, but in cattle the incidence was slightly less than in 1929. The chief work of the Research Institute of the College at present is the investigation of Jöhne's disease and of mastitis.

After-care for Voluntary or Temporary Patients

The Mental After-Care Association, which has co-operated with the London County Council by receiving in its twenty-three cottage homes patients under reception orders who are absent on trial from mental hospitals, and by providing convalescent treatment following discharge, has informed the Council that it is prepared to extend these facilities for those who have been voluntary or temporary patients. The London County Council believes that this is very desirable, and has agreed to pay in respect of such patients 30s. a head a week, with a capitation fee of 5s. This weekly charge covers inspection by a local medical practitioner on the arrival and departure of the patient, but anything in the nature of medical treatment while the patient is in the home is subject to an additional charge.

Mental Observation Wards in London County Hospitals

At nineteen of the general hospitals and institutions now under the control of the London County Council there are mental observation wards. The total bed accommodation is 270 for males and 285 for females, and the number of patients passing through the wards in the most recent year totalled 7,224. The Central *Public Health* Committee now states that small wards, such as some of those which were instituted by the boards of guardians, are not satisfactory, and that the segregation of mental patients into larger groups offers better opportunities for treatment, as well as facilitates nursing and general administration.

As opportunity offers, therefore, patients are to be withdrawn from these unsatisfactory units and transferred to more suitable accommodation Proposals have also been formulated for the establishment of a regular consultative service by members of the medical staff of mental hospitals who are fitted to act as consultants in this respect It is proposed that such a service shall cover the observation wards at ten of the general hospitals and public assistance institutions The consultants chosen will act in this capacity without detriment to their duties in the mental hospitals service, but will receive further remuneration —at the rate of two guineas a session for one session weekly—for their consultative services

Ireland

Medical Benefits in Belfast Workhouse

As the result of a conference between representatives of the Ministry of Labour, the guardians, and medical officers, in regard to the recognition of two visiting medical officers as panel doctors for the treatment of the resident insured staff and the issue of certificates on behalf of insured patients, the guardians decided to recommend to the board that they should take no responsibility for certification, and suggested that the Joint Finance and Medical Charities Committees, which were dealing with the question under the medical benefits scheme, should be requested to consider the question of the working arrangements, so as to facilitate treatment of the officers concerned In moving the adoption of the report of the conference, Mr John Wilson, J P , said it would be unfortunate if they had to bring in outside medical officers The Government had agreed that two medical men should be appointed, and in October last year the Ministry wrote approving the agreement The question of certification had arisen, and it had been ascertained that the medical staff had been paid for their services, although no provision had been made under the Medical Benefits Act, with the result that the doctors applied to the board for an increase in salary The guardians then ascertained for the first time that the resident medical officers were being paid substantial sums for certification by the Ministry The representatives of the Ministry, Mr Wilson pointed out, had simply said that under the Act which in England gave power from the first to embody medical benefits no provision was made for persons receiving treatment in such institutions as the Belfast workhouse, but that some special arrangement had been made in Northern Ireland by which the certification was paid for The guardians had no money to pay for certification, and the Ministry said that unless the guardians gave certification for nothing they would receive nothing The chairman said that the appointment of the guardians' own medical officers was the only satisfactory and logical way of dealing with the matter Apparently that had been approved by the Government in 1930 and now, almost nine months later, the Government had done nothing

Public Health in County Galway

In his annual report for 1930 Dr B O Beirne, county medical officer of health and chief school medical officer for County Galway, states that the county comprises an area of 1 596 505 acres, and that the population at the Census of 1926 was 169,366 Under the county scheme the institutions provided are a county hospital at Galway, a county home at Loughrea, and a mothers and children's home at Tuam In addition, there are four private homes in the town of Galway The county hospital at Galway is divided into three departments a medical and surgical hospital (220 beds), a fever hospital (60 beds), and a maternity hospital (18 beds), all of which have modern equipment The Woodlands Sanatorium, standing in its own grounds of seventeen acres, is at Renmore, about a mile from the town, and affords accommodation for forty nine patients Since May, when the new system was inaugurated, there have been 200 notifications by local medical officers of infectious diseases, in which typhus, typhoid, and diphtheria form a serious part According to the report, public opinion in the county is now alive to the importance of a pure water supply in the rural as well as in the urban areas The Board of Health has done much in this direction, and if the work progresses as it has during the past nine months a wholesome water supply should soon be available The Board of Health has also given much assistance in improving existing sewerage works and in providing new systems throughout the county In Galway City houses are being built on all sides and a scheme for the erection of houses in the Claddagh area for the working classes is in progress

Down County Mental Hospital

In the sixty first annual report of the Down County Mental Hospital, Downpatrick, Dr M J Nolan, resident medical superintendent, states that during 1930 65 males and 70 females were admitted, 25 males and 33 females were discharged, and 32 males and 23 females died, with the result that on December 31st there were 408 men and 388 women in the institution At no time in the history of the hospital had the recreation of the patients received so much attention Indoor and outdoor amusements such as concerts, dances, hockey and football matches garden parties, and cinemas, averaged almost three weekly Particular attention was given also to individual tastes and hobbies so that, apart from the associated entertainments, patients were encouraged to divert themselves in the ways they desired Some chose music and had their own instruments, others handicrafts, such as fretwork and painting while others took up games The radio was much appreciated, especially by those patients who were engaged in farming during the day, and then listened in to their own set in the evening

Correspondence

LORD KNUTSFORD REMEMBRANCE FUND

SIR,—I hope that the committee of the London Hospital will not be accused of making Lord Knutsford's death the pretext of an appeal for funds

A letter has been received at the hospital enclosing a donation of £1,000, and urging that a fund in remembrance should be started This is but one instance of a very general desire Very many other gifts for the same purpose have already been received, as have a number of letters asking for an opportunity to contribute We know too that collections by groups of workers are being made spontaneously The committee has therefore decided to open a ' Lord Knutsford Remembrance Fund

There were, at the moment of his death certain very necessary additions and improvements on which he had set his heart and to which he had contributed generously but which he did not live to see completed It is proposed to devote gifts sent in remembrance to the completion of these objectives, which include a new massage and electrical department new stores additional maternity beds and maintenance and a hostel for students

Will all who wish to honour the name and work of a very great man please send their contributions to the Treasurer, London Hospital, E 1?—I am, etc ,

EDWARD J MANN,

London Hospital Aug 17th Dean

The Public Medical Journal

SOME RECENT POLICIES REGARDING PARTICULAR DISEASES

Sir,—Had the term "psittacosis" not been applied to the more or less peculiar type of influenza which occurred in the winter 1929–30 there would have been no necessity to impose prohibition of importation. As in my opinion, which is stated below, the absence of psittacosis is in no way due to this measure, the difficulty of choosing the safe moment to let parrots in again, referred to by Sir George Buchanan, does not arise. The wave of influenza which occurred in the winter 1929–30 was due to the activity of the *B. faecalis alkaligenes*, and it was peculiar in so far as it happened to be the last of a cycle of some years. Whether its being the last was due to the ultra-microscopic phase of this bacillus causing the demise of the parent micro-organism (lysogenic action) or to its being the end-stage of a life-cycle requiring a period of quiescence to develop into the bacillary form is uncertain. Anyhow, the *B. faecalis alkaligenes* suddenly vanished from the excreta of man and animals in June, 1930, and it has been an absentee since. Its place was taken by the non-motile and motile forms of the bacillus of epidemic jaundice; and the three waves of influenza occurring since, in the summer 1930, the winter 1930–31, and the summer 1931, have been caused by the activity of these micro-organisms, aided by that of *B. acidi lactici*, *B. lactis aerogenes*, and *B. friedlander*.

Cases of influenza occurring before and since the winter 1929–30 have been encountered to which the term psittacosis could legitimately be applied. When the various micro-organisms responsible for influenza acquire pathogenic activity they do so in animals as well as in man. Climate seems to be the chief stimulus, and it is aided by faulty feeding in man and captivity in animals. Infection is not conveyed from animals to man or vice versa in the way universally considered. Epidemics and epizootics arise through the dissemination of activity, and they can be prevented and checked by the employment of the same activity. No groups of man and no particular animal are to blame, hence it is useless and needless to segregate the infected, to prohibit importation, or to slaughter the victims. If the interpretation of my results is correct there will be no psittacosis for many years. The wave of influenza occurring in the winter 1931–32 will be mild but a little more severe than that of the previous winter, and epidemics will occur in it which will be labelled "paratyphoid." But they will not be caused either by contaminated milk or water; they will arise as a natural sequence of events.—I am, etc.,

J. E. R. McDonagh.

London, W.1, Aug. 14th.

CONVULSIONS DURING ETHER ANAESTHESIA

Sir,—I have read the interesting communication of Dr. W. M. Priest in the *Journal* of August 8th, on the subject of ether convulsions.

In the last five years I have had the good or ill fortune to encounter the condition five times. On two occasions the complete picture of generalized clonus was presented; the remaining three were incomplete in that, recognizing their significance, I was able to curtail them by lightening the anaesthesia. All my cases occurred in deep anaesthesia, and I agree with Dr. Bloomfield's contention that true ether convulsions occur only in deep narcosis. In only one case was there definite sepsis, and in no case was there initial cyanosis. Four patients were young women; the fifth, a female child. I observe that Dr. Priest's patient was also a woman, and I am tempted to suggest a definite sex susceptibility to the condition.

The orderly sequence of events, from clonus of the muscles of the face and neck to that of the upper limbs, trunk, and, finally, lower limbs, suggests a fit of cortical origin, and our problem is to discover its cause. Before advancing a theory I should like to recall a fact familiar to all anaesthetists. After prolonged and deep ether anaesthesia it is not unusual for the surgeon to complain of renewed bleeding from tissues in which he has accomplished primary haemostasis. This bleeding is sufficiently marked to suggest an active capillary dilatation. It is known that histamine, on injection, is capable of producing such a condition by paralysing the capillary wall; but what is more significant is the following, quoted from Samson Wright's *Applied Physiology*: "In unanaesthetized animals ten times the dose of histamine is necessary." Again, Lewis has shown that injuries to the skin cause the liberation of substances of histamine-like action. In a surgical operation we have all the factors for a histamine effect, the trauma producing the histamine bodies and the anaesthetic augmenting their action.

I would advance the theory that increased vascularity of the cortex cerebri, more particularly of the Rolandic area, produced by such a histamine effect, is the underlying cause of ether convulsions. That these convulsions occur with ether rather than with chloroform may be due to the fact that the latter drug tends, of itself, to produce cerebral anaemia, and we hear that some workers have employed chloroform with success in the control of ether convulsions.

I realize that to test the theory one should attempt to produce a convulsion by injecting histamine into a deeply etherized patient. I confess that it would require a bolder man than I, and I am certain that no surgeon would welcome such activities on the part of his anaesthetist.—I am, etc.,

L. T. Clarke.

The Queen's Hospital, Birmingham, Aug. 17th.

TREATMENT OF DYSMENORRHOEA

Sir,—I see that Mr. Venn Dunn suggests, in his letter in the *Journal* of August 8th, that I was "speaking for the Medical Women's Federation." I do not know how he got that impression, and I hasten to correct it. The views expressed in my letters were not intended to voice the opinion of that or of any other medical association to which I belong, but were the results of my own individual experience. It happens that many members of the Medical Women's Federation do not endorse my views on the treatment of dysmenorrhoea. I must therefore ask Mr. Venn Dunn to note that I made no reference to the Federation in my letters.—I am, etc.,

Alice E. Sanderson Clow.

Cheltenham, Aug. 12th.

REFRESHER COURSES FOR SHIP SURGEONS

Sir,—In view of the fact that special courses for ship surgeons are about to commence, it may be desirable for the members of the staffs of the medical schools concerned to consider the experiences of individual ship surgeons who have found their ordinary medical training insufficient for all the emergencies at sea. The ordinary medical course, for example, has little to say about seasickness, and so the barber's shop may be found in competition with the surgeon where the treatment of mal-de-mer is concerned.

One task occasionally falls to the lot of a ship surgeon, in which he has had no instruction, and often no previous experience—the embalming of a dead body. In these days of luxurious ocean travel many persons undertake voyages when not in good health, and deaths at sea are not rare. In such cases sea burial is an easy means of disposal, but quite often it is the wish of the relatives that the body should be embalmed and brought home, especially in the case of American citizens.

The ship surgeon must therefore be prepared to undertake some form of preserving process, and, although he cannot compete with the professional embalmer, he should make sure that he has an efficient preservative solution and the means of injecting it Failure to prevent post-mortem changes, in addition to bringing discredit to the shipping company, reflects on the efficiency of the sea going members of the medical profession Although embalming is not usually considered to be a doctor's work, the ship's doctor should remember that he may have to do it, and would therefore be well advised to know something of its technique A demonstration of embalming methods might well be included in the proposed refresher courses —I am, etc ,

Liverpool Aug 9th C Allan Birch, M D , M R C P

DOCTORS AND ROAD ACCIDENTS

Sir,—Towards the end of a long discussion at the Annual Representative Meeting (*Supplement*, July 25th, p 64) Dr Bone said that he believed that every police man in Brighton carried in his pocket a voucher, which he handed to the doctor who was summoned to an accident, whether the doctor was called by the policeman or somebody else, and the Brighton Corporation paid a fee to the doctor He believed Willesden and Gateshead had similar schemes

So far, so good , but can anybody tell me how it comes about that public money can be used for such a purpose ? Do the police collect the fees so paid by the corporation from the people who are involved in these accidents? If not, why should the taxpayer have to be penalized? Is it legal?—I am etc ,

Pelton Aug 16th Robert A Welsh

Medico-Legal

USE OF THE TITLE " DENTAL SURGEON "

In the Chancery Division, before Mr Justice Farwell on July 21st and 22nd, the case was heard of the Attorney General (suing on the relation of the British Dental Association) *v* Weeks in which a declaration was sought that the use of the title or description " dental surgeon " by Mr Wilfred Henry Weeks, Dentist 1921," practising at Norwich was reasonably calculated to suggest that he had a professional status or qualification which he did not in fact possess and an injunction was asked for restraining him from using that title The defendant contended that he had a right to use the title because to the man in the street there was no distinction between the words " dentist " and " dental surgeon ' and that as he was entitled to practise dental surgery he must be entitled so to describe himself

Mr Gavin Simonds K C , for the plaintiff said that previous to the Act of 1921 no one could legally call himself a dental surgeon unless he was registered under the Act of 1878 either as having a degree diploma or licence, or as having been in practice in 1878 The Act of 1931, while it expressly permitted the terms ' dentist " and dental practitioner, did not permit the term " dental surgeon ' More over ' dental surgery " in the case of all examining bodies was that in respect of which a degree or licence was given It was believed that with the exception of the defendant no one of the 6 858 ' Dentists 1921 ' on the *Register* so described himself No case was found in the London *Telephone Directory* of a Dentist 1921 " who called himself dental surgeon ", but with few exceptions dentists who had the qualification of a degree did so describe themselves

Sir Francis Dyke Acland chairman of the Dental Board who gave evidence on subpoena saying that he did not wish to take sides as between the two sections of which the *Dentists Register* was composed said that the title imported a person who was a licentiate with a slight exception in the case of the men who came on the *Register* in 1878 of whom there were still 428 In their case the announcement did not imply possession of a degree Sir Norman Bennett president of the British Dental Association said that the term " dental surgeon " grew up contemporaneously with the growth of dental hospitals The earlier term was " surgeon dentist," still used in connexion with the royal appointment but the other term replaced it as being more in line with other specialties such as " ophthalmic surgeon " The term suggested to him qualification by possession of a licence Colonel Norman King registrar of the Dental Board, said that the term conveyed to him the idea of a person who was on the *Register* otherwise than under the Act of 1921 Mr B J Wood, chairman of council of the British Dental Association, gave similar evidence as did six other dental surgeons and one " Dentist 1921 " from various parts of the country

Sir Humphry Rolleston agreed that the title implied possession of a degree or diploma Asked whether in his own profession the possession of a degree was not very commonly announced by the letters, Sir Humphry said that much depended upon the temperament of the man , he thought it rather the exception for a man to put " M D " or " M B " on his plate Sir Holburt Waring testified similarly saying that apart from Mr Weeks, he had not come across any case of a " Dentist 1921 " who so described himself

Mr A Grant K C , for the defence first called Mr Fred Butterfield, secretary of the Incorporated Dental Society, Ltd and a member of the Dental Board Mr Butterfield said that he had inspected the signs of a number of members of the British Dental Association registered by virtue of having been in practice in 1878, and having no degree or licence, on which the name " dental surgeon " appeared He also said that he could give half a dozen names of " Dentists 1921 " who used the title The judge told Mr Butterfield he must produce these names and on the following day he produced one name from Scotland, eight from Ireland (men registered on the British *Dentists Register*, but transferred to the Irish *Register* on the formation of the Irish Free State), and one from England—namely, the present defendant Mr Peyton Phelps of Upper Norwood registered as an " 1878 man," gave evidence saying that he described himself as a dental surgeon, and did not think the words connoted licentiateship Mr P W Raffan a former member of Parliament said that in Lancashire it was customary for a person who possessed degrees to announce them and when " dental surgeon ' was stated it meant generally that the man possessed no degree Evidence was also given by a journalist the secretary of a friendly society, a justice of the peace a retired civil servant, an employee of Lloyds and a compositor all of whom stated that to their minds " dental surgeon " did not imply a degree

Mr Grant claimed that it was the man in the street who was the judge If other people by virtue of their special knowledge, read something more into the term weight should not be attached to their evidence The Act of 1921 was to be read with the Act of 1878 in which latter the words "dentistry ' and "dental surgery " were synonymous Unless there was something in the 1921 Act which in terms prohibited a person from calling himself a dental surgeon it was absurd to suggest that it was misleading or improper for him to do so

Judgement for Plaintiff

Mr Justice Farwell gave judgement for the plaintiff, and granted the declaration and injunction asked for He said that the case was of importance both to dentists and to the public The Act of 1878 was not aimed at preventing persons practising as dentists (save to the extent that it made it impossible for them to sue for their fees) but at preventing persons who did not comply with its requirements from describing themselves as dentists For the first time it required persons who desired to call themselves dentists or dental practitioners or by any like title to be registered As a result the persons registered included both those qualifying by degree and those who without a degree were in practice in 1878 The latter class was diminishing numbering now some 400 on a *Register* of 14 000 These persons were often described as dental surgeons or surgeon dentists The 1921 Act was a complete departure from the earlier Act because it prohibited the practice of dentistry by the unregistered Witnesses had been called on the one side to the effect that the title connoted a degree or diploma , on the other side, that it did not The evidence showed that it was not unusual,

though not universal for persons possessing a degree to announce it by the appropriate letters, also that, with one or two exceptions, the men who registered under the 1921 Act did not call themselves dental surgeons That Act, when it provided for the description to which a registered person was entitled did not use the title in question in this case He therefore started with this, that up to 1921 there was a class of persons who could properly be described as dental surgeons and no other class of persons to whom that description could be applied When the Act of that year permitted another class of persons altogether to be entered on the *Dentists Register*, and did not provide that they should be entitled to describe themselves as dental surgeons, it must follow that for a "Dentist 1921" to call himself a dental surgeon was calculated to suggest that he possessed a professional status or qualification which in fact he did not possess If the legislature had intended that it should be open to anyone who registered under the Act of 1921 to call himself a dental surgeon, he could not help thinking that it would have said so in terms The judge added that he did not form his judgement on the evidence called for the plaintiff or for the defendant He could not disregard that evidence on one side or the other, and he thought the inference to be drawn was that while to a great many people the words "dental surgeon" meant nothing in particular, to a considerable number they had a special significance In face of the evidence called for the plaintiff it was impossible to say that this was a description not reasonably calculated to suggest a certain status, but he based his judgement on the strict interpretation of Section 4 of the Act of 1921, relating to titles and descriptions

Leave to appeal within twenty-one days was granted

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Home Office Estimates

On a vote for expenses of the Home Office, on July 29th, Mr. G LOCKER LAMPSON called attention to the treatment of mental defectives who were brought before the courts He said the Home Secretary could do a great deal by communicating with the magistrates There was a practice in some courts of sending persons of doubtful mentality to prison to undergo observation Some magistrates took advantage of their powers under the Mental Deficiency Act, and others did not, but sent mental defectives to prison as convicted prisoners It was undesirable that mental defectives should be branded as convicted felons and that prisoners of normal mentality should be in the same prison with mental defectives Short sentences could not possibly do mental defectives the slightest good, they ought at once to be sent to a special institution Often delay took place in getting the person into an institution, and that was one of the causes why those people were sent to prison, where they languished perhaps for months, until accommodation in an institution could be found In many cases the sentences expired before accommodation was found, and these mental defectives were once more thrown on the world, after doing their spell in prison to commit further wrongs against the community

Lord E PERCY said that although there had been an increase in the number of factory inspectors it was not sufficient to render Home Office inspection of factories what it ought to be In many industries they might get more rapid advance and more easy adaptation to the new discoveries of science if they delegated more responsibility from the Home Office to industry and made it answerable for the maintenance of a high standard of safety, health, prevention of industrial diseases and so on

Mr CLYNES, dealing with the treatment of mental defectives, said that as soon as a prisoner was found certifiable, the case was notified to the Board of Control, which communicated with the local authority and arranged as soon as possible for the *transfer of that prisoner to an institution for mental defectives* Considerable numbers of prisoners, although not certifiable were recognized by the medical officers as of sub normal intelligence or as having a defective sense of responsibility The treatment of those persons in prison was a matter to which most careful consideration had been given Those who were serving sentences of any length were transferred to certain selected prisons for special arrangements to be made about their treatment and occupation In all cases special care was taken not to subject them to undue discipline He welcomed Lord E Percy's argument with regard to factory inspection The Home Office had for some time been following precisely those broad lines of adapting factory inspection to the changed industrial conditions, which had been enormously altered by big amalgamations, and because many factories and workshops had taken the place of smaller ones Adequate precautions conditions of safety, the setting up of elaborate welfare organizations within the works all tended to alter the service of the factory inspector and to make unnecessary for him to do the things he had to do fifty or sixty years ago There was still much good work for the inspector to do and the Home Office was not only endeavouring to follow on the lines of what Lord E Percy had said but to make a substantial increase in the number of inspectors in the lifetime of this Government In 1929 there were 200 inspectors, to-day that number was 282

Mr KELLY, referring to the chemical industry, said that in the case of aniline dyes many persons were affected by a serious disease He asked if consideration was given to the issuing of regulations under which such persons would be compensated in the event of their being disabled from following their employment There ought to be a closer investigation on the part of the inspectorate into the heavy as well as the light chemical industry

Mr SHORT said he would have inquiries made with regard to dyes to see if any further step could be taken in the direction Mr Kelly had indicated He had stated a few weeks ago that the names of medical referees under the Workmen's Compensation Act should be made more widely available If general access to them was required, he would see that that was done

The House agreed to the Vote

Housing

Mr GREENWOOD told Dr Fremantle on July 30th that his suggestion that an annual return should be published on the subject of housing detailing the number of houses in occupation the number of houses erected *during the year* the number of houses reconditioned and the number of houses included and dealt with during the year in clearance and improvement areas, would offer certain advantages if it could be issued very shortly after the close of the period to which it related This would, however be impracticable He would consider some way of amalgamating the different statements and returns that were compiled

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel Harry Herbert Brown R A M C (ret) died on May 2nd He was born at Knaresboro, Yorks on February 25th, 1862, and was educated at Aberdeen where he graduated as M B and C M in 1883 Entering the Army as surgeon on January 30th, 1886, he became lieutenant-colonel after twenty years service and retired on December 26th 1917 He served in the Burmese campaigns of 1887 to 1889, and received the Indian frontier medal with two clasps

Brevet Colonel Edward Nodin Sheldrake, late of R A M C and Grenadier Guards, died in London on June 10th aged 72 He was born at Ipswich on June 2nd, 1858 was educated at University College Hospital, took the M R C S and L R C P Lond in 1884, and after filling the post of resident house surgeon at University College Hospital, entered the Army as surgeon on May 30th, 1885 Four months later on October 7th, 1885, he was appointed medical officer of the Grenadier Guards, and put in his whole service in that regiment He served with his battalion throughout the South African war, 1899-1902, taking part in the advance on Kimberley, including the actions at Belmont Enslin Modder River, and Magersfontein, operations in the Orange Free State, including the actions at Poplar Grove, Driefontein Vet River, and Zand River, and in the Transvaal, including actions at Pretoria, Johannesburg, Diamond Hill, and Belfast He was mentioned in dispatches in the *London Gazette* of September 10th, 1901 and received the Queen's medal with six clasps, and the King's medal with two clasps He rejoined for service in the great war of 1914-18, and was promoted to brevet colonel on June 3rd, 1918

Obituary

WALTER ERNEST DIXON, M.D., LL.D., F.R.S.

Reader in Pharmacology, University of Cambridge.

Walter Ernest Dixon, who died suddenly and unexpectedly from cardiac failure on August 16th, at his house, The Grove, Whittlesford, near Cambridge, was one of the few pharmacologists in this country, and the loss to the University of Cambridge, where he had taught generations of students throughout this century, is calamitous. He was born on June 2nd, 1871, the younger son of the late Robert Bland Dixon of Darlington, his brother being Engineer Vice-Admiral Sir Robert Bland Dixon, K.C.B. Educated at Dulwich and St. Thomas's Hospital, where he was house-physician, he qualified in 1895 as M.R.C.S., L.R C.P., and took the degrees of B.Sc. (1891), M.B., B.S. (1896), and M.D. (1898). In 1899 he became assistant to the Downing Professor of Medicine (J. B. Bradbury), in 1902 received the honorary degree of M.A., in 1909 was appointed University lecturer in pharmacology, and ten years later Reader in that subject, resigning the professorship of materia medica and pharmacology at King's College, London, which he had held for a number of years On the death of Professor Bradbury in his ninetieth year in June, 1930, Dixon, who had for years carried on the teaching and directed research in the subject, was the natural successor to a chair he had long waited for, and therefore had probably refused to stand for similar positions elsewhere. The Downing chair, however, was suppressed, all professors elected after October 1st, 1924, automatically becoming emeritus professors at the end of the academic year in which they attain the age of 65 ; in these circumstances it is not surprising that the offer of a special chair in pharmacology did not appeal to one who was extremely active and could retain his Readership till the age of 70.

WALTER ERNEST DIXON

During the war, from 1915 to 1919, Dixon played a highly important and responsible part in the service of his country, which the rank of temporary Surgeon Lieutenant, Royal Navy, most efficiently camouflaged ; for this he was created O.B.E. Among his numerous activities was the discharge of public and sometimes laborious duties, especially on the League of Nations' Committee on Morphine and the Standardization of Biological Products, and as a member of Government committees, such as those on the preservation of foods, lead ethyl, and drug addiction, subjects on which he was a recognized authority. He had lately been a moving spirit in establishing at the Society of Apothecaries the Register of Bio-physical Assistants. He took a prominent part in compiling the first edition in 1907, and in revising subsequent editions of the *British Pharmaceutical Codex* ; and the establishment of the pharmacological laboratories of the Pharmaceutical Society was very largely due to his advice and guidance. His literary and editorial energies were remarkable: his *Manual of Pharmacology* went through seven editions between 1905 and 1929, his *Practical Pharmacology* (1920) was in process of revision, and his contributions to other combined works, including Allbutt's *System of Medicine*, Heffter's *Pharmacology*, Hale-White's *Textbook of Pharmacology and Therapeutics*, were noteworthy. His published papers on physiology, of which there were twenty-eight in the twenty-five years ending 1924 and a number since, cover a wide field of research ; many of them were in collaboration with his colleagues and pupils, and among these the contributions with the late T. G. Brodie on the nature of asthma will always stand out as epoch-making. Since 1926 he had been joint editor of the *Journal of Pharmacology and Experimental Therapeutics* ; he was also on the editorial committee of the *Quarterly Journal of Pharmacy and Pharmacology*, and of the *British Journal of Physical Medicine*. As an examiner he was much in request at the universities of England, Scotland, and Ireland.

As a remarkably attractive lecturer, and especially as an inspiration to those undertaking original investigation, he built up a School of Pharmacology at Cambridge and set an example of high ideals in this science which, with A. R. Cushny of Edinburgh, he had done so much to initiate in this country. He has now followed his friend behind the veil, but the start they made should enable their pupils to attain further success. While taking a broad view of the scope of pharmacology, especially in its application to clinical practice, Dixon held strong opinions about its independence as a science, and did not regard it as merely a branch of physiology. His personal characteristics were well suited for the head of a progressive department, for he was a kind-hearted man, with the valuable property of being able to express a decided opinion without raising resentful opposition. A warm and unselfish friend, an interesting companion who had travelled and seen much, he was charitable in the best sense, never made enemies, nor played for his own hand.

Dixon was elected a Fellow of the Royal Society in 1911, in 1930 a Fellow of the Royal College of Physicians of London under the special by-law providing for the election of men not members of the College but holding a medical qualification and distinguished in any branch of the science or practice of medicine, Academico Onorario, Reale Accademia Medica di Roma, and in 1911 an honorary member of the Pharmaceutical Society He was president of the Physiological Section of the British Association in 1929 when it met at Capetown and Johannesburg, and of the Section of Therapeutics of the Royal Society of Medicine ; last year he received the honorary degree of LL D from the University of Manitoba on the occasion of the meeting of the British Medical Association at Winnipeg, when he delivered a clinical address on drug addiction. He had recently been appointed Croonian Lecturer at the Royal College of Physicians of London. In 1907 he married Hope, daughter of Francis Glen-Allan of Dulwich.

H. D. R.

Professor Frederick Gowland Hopkins, President of the Royal Society, in an appreciation of Professor W. E. Dixon's work, writes:

Dixon's scientific interests were of the widest, and his activities as an investigator correspondingly diverse. He heartily believed that pharmacology deserved an independent status in any formal classification of the sciences; but, recognizing its intimate contacts with organic chemistry, physiology, biochemistry, and pathology, as well as with practical therapeutics, he held that in it, more than in most subjects, specialization should be avoided, alike by the teacher and the investigator. His own researches were far from specialized, a circumstance that makes it the less easy to deal with them briefly.

His earliest serious research, carried out while holding a Salter's Research Fellowship at St. Thomas's Hospital, dealt with the physiological action of preparations from the mescal plant. This was published in 1898. He himself experienced the well-known visual hallucinations produced, and, in later years, would frequently describe them vividly. Shortly afterwards he worked with cannabis indica, and at that time believed it to be a drug of which more use might be made. He moved to Cambridge in 1900, when he was working with Brodie on vascular changes in the lung, a subject which long continued to interest him. Dixon himself later studied the vascular mechanisms of the testis, showing that there was definite vasomotor control in the organ, though the vascular changes involved were of small magnitude. This work led him to study the action of orchitic extracts and of Poehl's spermine. The results obtained with the former we now know to be somewhat less specific than he then thought; the latter he found closely to resemble choline in its action. Shortly after this he published a valuable paper on the innervation of the frog's stomach studied on pharmacological lines. The early work with Brodie already referred to led, in 1904, to the conjoint publication of an important paper on the innervation of the pulmonary blood vessels. It described the use of a highly original technique, and discussed the influence of many factors. The authors came to the definite conclusion that the arterioles of the lung possessed no vasomotor nerve supply. About this time, and a little later, Dixon was engaged in urging the desirability of the biological standardization of drugs, and did a good deal of work to illustrate its importance. His later work can be now dealt with under various special headings rather than chronologically.

First may be mentioned the classical experiments carried out with Halliburton on the cerebro-spinal fluid. The factors concerned with secretion of the fluid were first studied, and, among other significant facts, it was shown that extracts from the choroid plexuses contained a specific cerebral lymphagogue. The cerebro-spinal pressure was next thoroughly studied, and the great importance of secretory activity in determining this was demonstrated. The effects of increase in the pressure were later followed in detail, and, finally, a specially interesting paper described experiments upon the circulation of the fluid. The extreme rapidity with which substances introduced into it appeared in the blood, while diffusion in the opposite direction scarcely occurred, were points emphasized; and the conclusion was drawn that it was by the blood, and not by the lymph, that the fluid which was constantly being excreted found its main exit from the cranio-vertebral cavity.

As already mentioned, Dixon was always interested in pulmonary phenomena. The finding of Brodie and himself that the vessels of the lung were not innervated led "to the publication of some fifty to sixty papers dealing with the subject directly or indirectly, of which about half supported the findings of Brodie and Dixon." I quote Dixon himself. He was unconvinced by the evidence contained in the other half of these papers, and three or four years ago he reinvestigated the subject with a pupil and colleague, J. C. Hoyle. Having eliminated cardiac effects, which he held to explain the opposed results of others, he became convinced that these later crucial experiments demonstrated that there was no effective pulmonary vasomotor supply. Any slight effects observed were of a "vestigial" character.

In 1903 he had published, again with Brodie, the results of three years' researches upon the bronchial muscles, which led, *inter alia*, to the firm belief that spasm of these muscles was the fundamental cause of acute attacks of asthma. This view is more general now than it was then. Nine years later he published, with F. Ransom, a careful study of the innervation of the muscles, and more recently gave occasional attention to other aspects of the subject. In quite recently delivered lectures and addresses he showed that, as the result of his own studies, he attached little importance to the allergic aspects of asthma.

In his early days he had been a student of Brown-Séquard's publications, and became interested in organotherapy before it was fashionable. He always followed with care the literature of endocrinology, and in his routine work became exceedingly familiar with properties of all the glandular preparations on the market. In 1910 he attempted, with Halliburton, to throw light on the functions of the pineal body, though without success. In 1923 he published a paper on the pituitary gland, showing that it secreted into the cerebro-spinal fluid, and was specifically excited to secretion by ovarian extracts. In the following year, with F. H. A. Marshall, he showed that this effect of the ovary was only to be observed when corpora lutea were absent; when they were present the authors found that its action on the pituitary was completely negative. They found also that the ovarian secretion did not act directly on the uterus, while that of the pituitary specifically acted on the uterine muscle.

Dixon published a number of papers on the action of individual drugs—cocaine and colchicine, for instance, and the various artificial derivatives of quinine. His researches on more than one occasion dealt with the effects of alcohol on the body. He was alert to the advances in chemotherapy, and kept in close touch with the subject. He investigated several cases bearing on the relation between chemical structure and physiological action, though inclined to be sceptical as to the closeness of this relation. One case studied by him showing the influence of a form of isomerism, which is itself unusual, was of special interest. Of two di-methyl telluronium dichlorides with apparently identical structure, one was relatively inactive, while the other powerfully and specifically stimulated the suprarenals.

He was always attracted to the more physical explanations for action of drugs, and took much interest in Straub's view concerning the action of muscarine on the heart—namely, that it is caused by the physical process of the passage of the drug through the limiting layer of the cell; once it has passed this it has no further action. Dixon sought for further instances to support such a view, and thought he had done so—for example, in the case of volatile substances, which exert a common action, though of different chemical nature.

No reference has been made to papers published by others describing work done under Dixon's inspiration. His influence was exceedingly stimulating to his pupils, and he was abundantly generous not only with advice, but with practical personal assistance. His mind was always

ull of fresh and original ideas, and if it may be said hat they were, not infrequently, too good to be true, hey led to many investigations, and their discussion kept ilive a spirit of optimism in his department which was nvaluable.

Dr. ALFRED COX, Medical Secretary of the British Medical Association, writes:

As I write this I know nothing of the circumstances of Professor Dixon's death, except that it was sudden. Certainly none of us here had any idea that there was anything wrong with his health, and the news came as a terrible shock. Dixon was always so full of life and the joy of life that it seems almost impossible to think of him as gone. It is a trite thing to say that a man will be missed, but it is certain that there are few men who will be more missed from the ranks of the Association than Dixon, for he filled a particular niche and filled it so completely that it is difficult to think of anybody else being in his place. On all scientific affairs he was a tower of strength as an adviser. The Association is accustomed to see busy men put everything aside for its work, but I can truly say that I have never known anybody more willing than he was, or who did his favours to the Association with such unaffected pleasure and graciousness. For many years, along with Sir Humphry Rolleston, he has been our chief adviser in regard to scholarships and scientific grants; but the other ways in which he made himself useful to the Association are innumerable. He was a very influential man in many directions, and he never failed to use that influence on behalf of the Association. He was emphatically "a good B.M.A. man," but in addition he radiated an atmosphere of good humour and cheerfulness that made him acceptable at all times. He was like a breath of fresh air in a committee, and he managed to combine scientific outlook with humour, good fellowship, and helpfulness in a way which is, in my experience, almost unique. Dixon loved the Association and was proud to know that his affection was returned by those among whom he worked, and now that he is gone I am glad to think that the last honour bestowed upon him was the LL.D. of Manitoba University, which he received with ten others at our Winnipeg Meeting. He thoroughly appreciated the honour, and its conferment gave a kind of personal pleasure to every member of the Association who knew Dixon at all well. I have unfortunately in my time had to write a good many notes of this kind, to mark the loss of a dear colleague or of a valued worker for the Association. Very rarely have I felt such a sense of personal loss, and I know this feeling will be shared in quite unusual degree by very many members of the medical profession.

JOHN ROBERT LORD

JOHN ROBERT LORD, C.B.E., M.D.,

F.R.C.P.Ed.

By the death, on August 9th last, of Dr. J. R. Lord, medical superintendent of Horton Mental Hospital, psychiatry, and especially organized British psychiatry, has lost one of its most prominent figures and devoted workers. Both in his own hospital and in manifold outside activities, he gave himself unstintingly in the cause of the prevention and better treatment of mental ill-health.

Dr. Lord was born in 1874 at Blackburn, and was educated at the Blackburn Grammar School, and later at Owens College, Manchester. He took his medical course at Edinburgh University, where he had a brilliant career; after qualifying M.B., C.M. in 1896 he was appointed demonstrator of pathology. Psychological medicine, however, claimed him—as it did his contemporary Sir Hubert Bond and many others who had come under the influence of Clouston's teachings—and in 1897 he was appointed assistant to Dr. Goodall at Carmarthen Asylum. For his research work at this institution he was awarded the bronze medal of the Medico-Psychological Association. The following year he joined the service of the London County Council at Hanwell. He was soon transferred to Bexley, then the newest of the London county mental hospitals, and took a full share in the pioneer work being carried out there in the provision of admission and convalescent units, and of other modern improvements. His promotion was rapid, and in 1907 he was appointed medical superintendent of the Horton Mental Hospital at Epsom.

From 1907 to 1914 Dr. Lord devoted himself chiefly to the modernization of his institution. It was his aim that it should be "run on general hospital lines," and he brought it to a high pitch of efficiency. Laboratory work was developed, and facilities for the treatment of recent cases were extended. The new admission hospital, opened in 1912, was largely of his own planning, and it has been taken as a model by a number of other mental hospital authorities. In 1915 Horton became the County of London War Hospital (later known as the Horton War Hospital), and Dr. Lord became its commanding officer, with the rank of lieutenant-colonel. In his *Story of Horton War Hospital* he has given a detailed and illuminating account of how a mental hospital was in a short time successfully converted to military use, and of its subsequent administration. For his war services he was awarded the C.B.E. in 1919.

After the war Dr. Lord threw himself whole-heartedly into every reconstructive scheme that had as its object the raising of psychiatric practice to a higher level. At Horton occupation therapy was introduced, and a greater

degree of freedom was allowed to patients. Malarial treatment of general paralysis was begun at an early date. Under the Ministry of Health a research station was established at Horton which supplied mosquitos to other treatment centres throughout the country, and from which much valuable work has emanated, not only on general paralysis, but also on the transmission and treatment of malaria itself.

Dr. Lord was a strong advocate of team work in dealing with recent mental cases; by specialization on the part of the medical staff, and by the employment of consultants, he sought to bring every branch of medicine to bear on each individual case. Between the physiogenic and psychogenic schools of thought he endeavoured to keep a due balance, and foreign visitors to his hospital recently had occasion to comment on the "polypragmatic" spirit of the institution.

He sought to enlighten the community in the problems of mental disease. He was among the first to appoint a social worker to link the hospital with the outside world. He welcomed visitors to the hospital, and on his appointment in 1928 as lecturer in clinical psychiatry to the London School of Medicine for Women he organized at Horton an unusually thorough course of instruction. The mental hygiene movement found in him a warm supporter; he was secretary of the National Council of Mental Hygiene, and spoke and wrote extensively on its behalf. Last year he attended the first international congress of mental hygiene at Washington, presiding at a number of the sessions, and was elected a member of the governing body.

Dr. Lord's connexion with the *Journal of Mental Science*, the organ of the Medico-Psychological Association, began in 1901 with his appointment as assistant editor; he became joint editor in 1911, and from 1915 onwards, as senior editor, he carried on not only the general direction of the journal, but nearly all the detailed and routine work. His own contributions were numerous, and many of his reviews were essays of value on psychological and psychiatric subjects.

To the Medico-Psychological Association itself he was a tower of strength. He took a large part in its educational and medico-political work, and had its interests constantly at heart. It was largely owing to his efforts that the association obtained a charter of incorporation and the designation "Royal." He was president in 1926–27, and his presidential address on "The clinical study of mental disorders" was a wide survey of contemporary tendencies in psychiatry as well as a detailed programme of hospital team work. Mainly at his instigation a research and clinical committee was formed, over which he presided, taking the liveliest interest in the work of the various sections. On the political side he rendered great service in preparing evidence for the Royal Commission on Lunacy, and, later, in connexion with the Mental Treatment Bill. His study of the history of the reception order did much to elucidate the purpose of judicial intervention in mental cases, and facilitated the abolition of such intervention in non-volitional cases. Mental nursing was another subject to which he gave much attention, and in 1929 he was appointed a member of the General Nursing Council.

His work brought him in touch with many foreign psychiatrists, and he was an associate member of several medico-psychological societies abroad. His opinion was often sought in such matters as the organization and staffing of psychiatric services overseas. In 1927 he was vice-president of the Section of Mental Diseases of the British Medical Association.

Although his last few years were burdened by a constant struggle with recurring illness, his energy remained undiminished; his disabilities seemed to spur him on, and his labours continued unremittingly almost to the day of his death.

Dr. Lord was a man of vigorous personality. Perhaps the most striking of his traits was his eagerness for, and obvious enjoyment of, his many activities. He had a high conception of the psychiatrist's calling. To his patients and staff he was the kindest of men; he was one of the staunchest and most generous of friends. In March of this year he married Dr. Ruby Carr, who was a member of the medical staff of Horton. Deep sympathy is felt for her in the very sad circumstances of her bereavement.

Dr. George M. Robertson writes:

I desire the favour of a few lines in which to express the admiration I had, shared with many other members of the Royal Medico-Psychological Association, for the late Lieut.-Colonel Lord. I do not have sufficient knowledge of his routine work nor of his numerous other activities to speak of these with authority, but I can speak of him as a friend and colleague in the Medico-Psychological Association, and in the Council of Mental Hygiene. An outstanding feature of his character that could not be overlooked was his unbounded interest and enthusiasm in the work and welfare of the association, which has been the means of placing our nurses and mental hospitals in the van of the civilized world. No time or trouble spent on its behalf was grudged by him. A phrase of this kind is often used in complimentary addresses and appreciations, but in Colonel Lord's case it has a special meaning. He held an important post under the London County Council, and this involved a full day's work. Every evening, however, after his official duties for the day were over, he began a second day's work for the association, working on till all the hours of the morning of the next day. The amount of work, mainly of a literary and organizing kind, that he did during these undisturbed hours in the evening and the night-time was colossal.

His official post in the association for many years was that of editor of the *Journal of Mental Science*, itself affording enough scope for the surplus energies of any ordinary man. He discharged the duties of this post, both from the business and scientific points of view, most efficiently, and enhanced the reputation of this journal. Some six years ago he was elected president of the association, and since then he has played an important, if not a leading, part in organizing its schemes and enterprises. Nothing that was done by the association was outside his interest and activities. The preparation of evidence for the Royal Commission, the presentation of the views of the association on the new Mental Treatment Act, the elaboration of a new constitution and laws for the association, now designated "Royal," these and similar operations were all influenced by his guidance. The training of mental nurses, their examinations, and their registration by the association was one of his chief occupations. A permanent memorial to his energy was the creation of the research committee of the association, whereby most excellent scientific work has been encouraged with success in our mental hospitals. He was secretary and an active member of the Council of Mental Hygiene, and at the International Congress at Washington last year he did further useful work for Great Britain.

Colonel Lord did the work of two men, and that under very unfavourable physical conditions. His state of health during all these years was critical. Being anxious on one occasion on account of his exhausted condition, I asked his niece, who then looked after his welfare, to order him to stop work. She answered sadly: "There is no living person who can get him to stop work." If ever a man died in harness, he did. Possibly he found distraction from the anxieties of his physical condition in hard work.

At all events, for years he was the most notable example known to me of a brave man struggling against adversity, refusing all compassion, and refusing to acknowledge defeat His work over, he now rests

[The photograph reproduced is by Vandyk, London]

Dr James Grierson Brown, who died at his residence, Stanley Road, Bootle, on August 5th, aged 80, was the senior practitioner in Bootle, where for forty years he was engaged in an extensive and widespread practice up to within a few weeks of his death Dr Brown was educated at the old Royal Infirmary School of Medicine, Liverpool, qualifying L S A in 1880, and later taking the M B degree of London Starting practice in Liverpool, he afterwards became associated with Dr Hill of Bootle, to whose practice he succeeded Dr Brown was of a reserved and retiring disposition, and took no active interest in public affairs but he was a devoted adviser and friend to his patients, who will find his place in their regard difficult to fill The interment on August 8th took place at Anfield Cemetery

By the death of Dr Charles Edward Hobbes on August 4th the Vale of Evesham loses one who had made himself beloved and respected by several generations of his patients Born at Belbroughton on April 5th, 1845, he was the fourth child and second son of Jonathan Lord Hobbes by his wife, Mary Anne Fosbroke His father died of typhoid fever while still a young man, and Hobbes was educated privately at Warwick, until seventy years ago he came to Bidford on Avon to assist his uncle, George Haynes Fosbroke, with whom he was afterwards in partnership He received his medical education at the Queen's Hospital, Birmingham, graduating L R C P and L M at Edinburgh in 1874, and obtaining the M R C S Eng and the L S A in the same year He then returned to Bidford, where he spent the rest of his life in a family practice which changed completely in the course of time Remote from railways and covering a wide area, it was carried out partly on horseback, partly in a high wheeled dogcart and gig, later by bicycle when the roads improved, and finally by motor car Through out his life he was a keen sportsman who rode regularly to hounds, was a successful competitor in horse jumping competitions, a first rate shot, and an excellent fisherman He was at one time keenly interested in craft masonry, served as Master of the Apollo Lodge No 310, and held office in the Provincial Grand Lodge Two or three years ago he retired to Broom, a neighbouring hamlet, where he employed himself in tending his flower garden, and a few months since went to Barford, near Warwick, to live with Mrs Oldham, his married daughter He married Mrs Scott of Weston, Stratford on Avon, who survives him with a stepdaughter and a daughter He was buried in the cemetery adjoining the church at Barford with a wealth of flowers, many of which were sent by the villagers of Bidford The Rev Thomas Parker, M A, paid a striking tribute to his worth on the Sunday after his funeral, directing attention to his modesty, his unaffected piety, and his readiness at all times to sacrifice himself for the good of his patients

It is with deep regret that we announce the death of Dr Katharine Maguire which took place on August 2nd at Fayrefield, Tyrrellspass, co Westmeath, to which she had retired in November last Dr Maguire was the youngest daughter of the Rev John M Maguire, rector of Boyle co Roscommon Her career as a student was very brilliant She was the first and only woman to win the Hudson Scholarship at the Adelaide Hospital, and she obtained first place at the M B, B Ch, and B A O examinations of the Royal University of Ireland in 1892, taking her M D three years later After qualifying she spent some time in Vienna, and then set up in private practice in Upper Mount Street, moving some years later to Merrion Square, where she remained till she ceased work Her kindness and sympathy for her patients, especially the poor, were unbounded Early in her career she opened a free dispensary for women and children in Harolds Cross, and, being much interested in housing, bought four tenement houses in Tyrone Street, managing them herself, and letting the rooms at a minimum rent All her tenants loved her, and at Christmas many of them had blankets, food, and clothes at her expense As lecturer on hygiene in Alexandra College for a long period she became well known as an exceptionally gifted teacher She was a member of the Academy of Medicine, and attended its meetings regularly, but her self effacing disposition did not often permit her to speak or to show cases In spite of her extraordinary devotion to her professional work, Dr Maguire found time to cultivate many other interests She had an ardent enthusiasm for women s political rights, and before the war was a keen but non-militant suffragette There are hundreds of people in Dublin to-day who feel they have lost a friend and adviser who can never be replaced

We regret to announce that Dr Arthur Seal Blackwell honorary secretary and treasurer of the Jersey Division of the British Medical Association, died on July 31st, at the General Hospital, Jersey, after a serious operation Dr Blackwell received his education at St Bartholomew s Hospital, taking the M B, B S Lond in 1892, and the M D Lond in the following year, in 1894 he became a Fellow of the Royal College of Surgeons, England At the end of the war, in which he held the rank of captain in the Royal Army Medical Corps, he resided in Jersey, where his skill as an anaesthetist was soon recognized Up to the time of his death he was visiting anaesthetist to the General Hospital Dr Blackwell had many outstanding qualities He was a gifted pianist, and his charming nature endeared him to his professional colleagues His death is mourned by a large number of friends and acquaintances, by whom he will be sadly missed

Dr Shepherd McCopwick Boyd died on August 8th at his residence, Springfield Avenue, Harrogate, where he was a past president of the local medical society After obtaining the Fellowship of the Royal College of Surgeons, Ireland, in 1883, he worked for some years in Manchester, and later at Bexhill, going to Harrogate about twenty-seven years ago Before the war he was surgeon captain in the Volunteers, and in 1914, although well over age, joined up and remained on active service until the armistice Early in life Dr Boyd established a great reputation by his athletic prowess He carried off trophies and prizes as a sculler in all parts of the United Kingdom, and on two occasions was a finalist in the Diamond Sculls at Henley To many of his friends, however, his outstanding quality was an extraordinary kindness of heart He took a special interest in the welfare of his junior colleagues, many of whom owe much to his friendly counsel at the beginning of their career He will also be remembered for his vigorous and attractive personality and for his consistently cheerful disposition, which remained unperturbed through the illness and deafness of his later years

We regret to announce the death in a nursing home at Ealing, of Mr Charles Richard Hewitt, at the age of 61 Mr Hewitt was well known as a librarian He entered the service of the Royal College of Surgeons of England in 1885 and was appointed assistant in the library in 1892 Mr James Blake Bailey being the librarian He served at Lincoln s Inn Fields until 1907, when he was appointed, jointly with Mr Archibald L Clarke, sub-librarian at the Royal Society of Medicine when Sir John Macalister was resident librarian As a sub librarian it was his duty to organize and rearrange the collections of books belonging to the various institutions which had amalgamated with the Royal Medical and Chirurgical Society to form a new corporate society In 1919 he resigned the post of sub-librarian, and accepted the invitation of the League of Red Cross Societies associated with the League of Nations in order to organize a Public Health Library at Geneva It was also proposed

to form an international institution of public health, and Hewitt was appointed registrar. The scheme came to nothing, but during the two years he was in Geneva he purchased and classified more than 5,000 volumes. Upon his return to England he became a member of the medical staff of Messrs. William Heinemann Ltd., and undertook the compilation of the *Medical Year Book*, of which two issues appeared. The object of the work was to classify members of the medical profession, a task which required personal knowledge of the medical profession as well as of its individual members. In 1925 he accepted the invitation of Dr. Henry S. Wellcome to become chief librarian of the Wellcome Historical Medical Museum Library, a position he held until his death on August 15th. In addition to his regular occupation Mr. Hewitt reorganized and recatalogued the library of the Medical School of University College, and was for a time librarian of Guy's Hospital Medical School. For five years he supplied the Royal Commission on Tuberculosis with periodical literature on the subject, and for this purpose sent more than 15,000 references. In 1900 he was asked to undertake the compilation of a "British Medical Index" to comprise all medical periodicals published in this country and the Dominions, a gigantic enterprise which was never completed. In 1906 he published a general index to the journal and reports of the Royal Institution of Cornwall, 1818–1906, and in 1911 he made an index of subjects and names in the New Sydenham Society's works. In addition to contributions to various learned and scientific periodicals he contributed to *Men and Women of the Time*, and in 1903 he wrote, in collaboration with Mr. B. Fletcher Robinson, a series of well-illustrated medical and scientific biographies dealing more especially with the *Vanity Fair* portraits by "Ape" and "Spy." He was a Fellow of the Library Association and of the Royal Historical Society.

Medical News

Sir John Simon will deliver the inaugural address of the session and present the prizes at the London (Royal Free Hospital) School of Medicine for Women on October 1st, at 3 p.m.

St. Bartholomew's Hospital old students' dinner will be held in the Great Hall of the hospital on Thursday, October 1st, at 7 for 7.30 p.m. Sir Percival Horton-Smith Hartley, C.V.O., will be in the chair.

The annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Trocadero Restaurant on Friday, October 2nd, with Sir William Willcox in the chair.

The annual general meeting of the Medical Sickness, Annuity, and Life Assurance Society will be held at the First Avenue Hotel, High Holborn, W.C., on Wednesday, October 7th, at 4.30 p.m.

The new session of the Medical Society of London will commence on Monday, October 12th. The annual general meeting will be held at 8 p.m., and at 8.30 p.m. Mr. Herbert Tilley will deliver his presidential address on "The laryngoscope in medicine." On October 26th, at 8.30 p.m., a discussion on blood transfusion will be introduced by Professor Alexander Fleming and Mr. Geoffrey L. Keynes. A clinical evening will be held on November 9th, at 8 p.m., and on November 23rd Sir Humphry Rolleston and Professor E. C. Dodds will open a discussion on the methods of determining liver function and their value. At the meeting on December 14th, at 8.30 p.m., a discussion on *x* rays in the diagnosis of thoracic disease will be introduced by Dr. P. J. Kerley, Dr. F. G. Chandler, and Mr. J. E. H. Roberts. The Lettsomian Lectures, on the reactions of the eye to general disease, will be delivered by Mr. F. A. Williamson-Noble on February 29th and March 7th and 16th, 1932. Sir James Berry will give the annual oration on May 9th, 1932, on "Fallen idols."

A tour of the Tower of London, organized by King Edward's Hospital Fund for London, will take place on August 26th, under the guidance of Mr. Walter Bell, F.S.A., who will give a short address on its history and associations and conduct parties round the building. The Bell Tower and Queen Elizabeth's Walk will be accessible to the party. Tickets, 7s. 6d. each, can be obtained from the secretary, King Edward's Hospital Fund for London, 7, Walbrook Street, E.C.4.

The Fellowship of Medicine and Post-Graduate Medical Association has arranged for the following special courses to take place in September: diseases of the chest, at the Brompton Hospital, from September 7th to 12th (fee £3 3s.); psychological medicine, at the Bethlem Royal Hospital, Tuesday and Saturday mornings at 11 a.m., from September 8th to October 3rd (fee £1 1s.); diseases of infants, at the Infants Hospital, from September 14th to 26th (fee £3 3s.); ophthalmology, at the Central London Ophthalmic Hospital, from September 8th to October 3rd (fee £3 3s.); medicine, surgery, and the special departments, at the Westminster Hospital (for men post-graduates only), from September 14th to 26th (fee £5 5s. for the course, or £3 3s. for either week). Syllabuses of the above courses may be obtained from the Fellowship of Medicine. A series of free lectures on "Prognosis" will begin early in October, and also the usual series of free demonstrations in medicine and surgery (one a week in each subject at different hospitals).

A course of post-graduate study in infants' diseases, with special reference to nutritional disorders and dietetics, will be given at the Infants Hospital, Vincent Square, S.W.1, from September 14th to 25th. It is designed for medical officers of welfare centres and others; the fee is £3 3s. The names of practitioners wishing to attend the course should be sent to the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1, to whom cheques should be made payable.

The first conference of the International Association of Preventive Paediatrics will be held at The Hague on September 7th and 8th, when the following subjects will be discussed: "The mortality within the first ten days of life, and the means of decreasing it," introduced by P. Lereboullet, Couvelaire, and Lacomme of Paris and A. Schlossmann of Düsseldorf; "Return cases of scarlet fever, and the means of preventing them," introduced by Fr. Von Gröer of Lemberg and A. Lichtenstein of Stockholm. Dr. H. Chodak Gregory has been invited to speak on the first subject, and Drs. J. D. Rolleston and B. Schlesinger on the second. Further information can be obtained from the secretary, Dr. R. P. Van Kasteele, Van Dorpstraat 20, Scheveningen.

The next International Congress of Medical Women will be held from September 15th to 22nd. The subscription is 30 francs. Further information can be obtained from the Association Internationale des Femmes Médecins, Elysée Building, Rue du Faubourg Saint-Honoré 56, Paris.

A course on diseases of the heart and blood vessels will be held at the Hôpital Broussais, Paris, under the direction of Dr. Laubry, from October 5th to 17th. The fee is 150 francs. Further information can be obtained from Dr. Matton, Hôpital Broussais, Rue Didot 96, Paris, 14e.

At the second International Congress of Light, held at Copenhagen, under the presidency of Dr. A. Rollier from August 15th to 18th, Sir Henry Gauvain introduced the discussion on the effect of light baths in tuberculosis.

A memorandum has been issued by the Central Bureau of Hospital Information on the conditions under which hospitals can obtain payment from insurance companies for the expenses of treatment of persons injured in motor accidents, under Section 36 (2) of the Road Traffic Act, 1930. Copies can be obtained on application to the director of the Bureau, 12, Grosvenor Crescent, London, S.W.1; single copies, 3d. post free.

King Edward's Hospital Fund for London has received a further donation of £500 from Lieut.-Colonel George Waters, I.M.S. (ret.), Bombay, who gave £1,000 to the Fund in 1928.

In connexion with the paper read by Dr. L. G. Irvine of Johannesburg in the Public Health Section at the Annual Meeting at Eastbourne on the control of silicosis in South Africa, it may be mentioned that a report of a symposium on the histo-pathology, pathological anatomy, and radiology of this disease, contributed to by Dr. F. W. Simson and others at a meeting in Johannesburg last October, has now been reprinted from the *Proceedings* of the Transvaal Mine Medical Officers' Association, and can be consulted in the Library of the British Medical Association. The various papers relate to the histo-pathology of silicosis, its pathological anatomy, and the correlation of its pathology, radiology, and symptomatology. An article by Drs. F. W. Simson and A. Sutherland Strachan in the *Journal of Pathology and Bacteriology* (vol. xxxiv, 1931), on asbestosis bodies in the sputum, has been reprinted in pamphlet form. A bacteriological and epidemiological study of pneumonia in the native mine worker of the Witwatersrand goldfields, by Dr. David Ordman, was published in the *Journal of the Medical Association of South Africa* on February 28th, 1931, and has now been reprinted in pamphlet form.

A medallion of Dr. Louis Bard, who was professor of clinical medicine at Geneva for twenty years, has been recently unveiled in the auditorium of the Cantonal Hospital at Geneva.

Professor Calmette has presented to the Forlanini Institute of Milan the sum awarded him as the decennial Roberto Rovichi prize for his method of antituberculosis inoculation.

Professor D'Arsonval of Paris has been nominated an honorary member of the Society of Medicine of Vienna.

A number of outbreaks of paratyphoid fever have recently been reported in various parts of Germany, the source of the infection being milk, cream, and especially ices.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62350 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

The secretary of the Royal Medical Benevolent Fund Guild writes that a beneficiary of the Royal Medical Benevolent Fund and Guild is in need of a bath chair, which the Guild is unable to supply. If any reader of the *Journal* could give assistance in this matter the committee of the Guild would be very grateful.

Treatment of Brittle Nails

"J. W." writes: Can any reader suggest a remedy for brittle finger-nails, which split when used for almost any purpose? The sufferer is a lady, over 60, who is now almost precluded from using her hands owing to this condition.

(?) Congenital Circumcision

"GLASGOW" writes: May I enlist your assistance regarding the frequency with which babies are born "circumcized." I have just seen a child of Jewish parents born fully circumcized, and I am told that such an occurrence, though of rarity, is occasionally seen in Jewish children. Is it commoner among them than among the children of non-Jews? The answer might throw a certain amount of light on the question of the inheritance of acquired characteristics.

Medical Treatment of Duodenal Ulcer

Dr. HAROLD AVERY writes: "Duodenum" (Scotland), in the *Journal* of June 27th, asked four questions with regard to treatment. (1) More rapid and more permanent results follow a carbohydrate regime. The products of meat digestion produce a copious secretion of gastric juice of high acid value. (2) Olive oil is far superior to any other vegetable or animal oil; the mineral oils, such as liquid paraffin, are of little use. (3) The alkaline powder is best taken from half to one hour after food. If "Duodenum" will have a fractional test meal examination he will be able to judge the best time to take the powder—about a quarter of an hour before the curve reaches its high level. (4) I have not found that prolonged alkaline treatment radically lessens the hyperacidity.

Lochnera Rosea

"PIPER METHYSTICUM" writes: With reference to Dr. John M. Dalziel's inquiry, I can give the following information. Nye and Fitzgerald (*Med. Journ. Austral.*, November 17th, 1928, p. 626) prepared a tincture of vinca leaves and tried it clinically. It had no appreciable effect on the fasting blood sugar, and did not diminish the rise of the curve after administration of glucose. They suggested that the beneficial effect claimed by some patients was due to the digitalis-like action of the preparation. An infusion is said to be the preparation used in Queensland and South Africa.

Painful Heels

Dr. REGINALD J. HANBURY (Foxbury, Woldingham) writes: The following personal experience may be of interest. At the end of last year, after suffering from a painful right heel for rather more than two weeks, I decided to try colonic irrigation by means of the "Suda" bath. A course of weekly baths was started in January, and after the second bath the pain, which had caused some lameness, was much relieved, and after the fourth bath had entirely ceased. The course was continued for a time with baths at lengthening intervals as a precaution against recurrence, and there has been no return of the pain. In my opinion the therapeutic effect of the colonic irrigation was supplemented by the marked diuresis which subsequently occurs, as well as by the mild diaphoretic action on the skin caused by the hot bath, which lasts about forty minutes. Previously ordinary dietetic measures and local applications had proved ineffective.

The Cigarette Habit

Dr. L. R. P. MARSHALL writes: In reference to the query by "Bungalow," in the *Journal* of August 1st (p. 230), for help to overcome excessive cigarette smoking, I found a soda-mint tablet kept in the mouth a great help to many young soldiers during the war, and also for private patients when cutting off smoking. They say it stops the desire, even when their companions are smoking.

"B. M. R." writes: In reply to "Bungalow," my advice is—reduce smoking gradually. First say, I must not smoke before breakfast; when this step is accomplished one begins to feel one has improved. The next step is no smoking before dinner or lunch. Now real improvement is achieved, but the will power must be exerted for the next step, which may be more difficult—no smoking before tea. One or two cigarettes after tea may be allowed, and the enjoyment of that smoke is marvellous.

Harvest Mites

"SUFFERER" writes: Living in the country for the past ten years, I and members of my family have been subjected to severe bites from some insect, commencing regularly during the first week in July and continuing until we go away on holiday in August. No sign of flea or other insect has been discovered in bedding. The bites appear to occur out of doors, and are confined to the after parts of the skin—bathing-drawers area, axillae, thighs, etc. The bites are intensely irritating, lasting for a week or so, and cause sleepless nights and restless days. I myself counted forty separate bites on my body recently. There are no animals about, but there are chickens some little distance from the house. At no other time of the year are we bothered with

bites. Any suggestion as to prevention would be very welcome, as the condition is such as to destroy comfort.

*** It would seem probable that the source of our correspondent's trouble is the "harvest-mite" or "jigger" (not to be confused with the tropical "jigger," which is a species of flea). These "mites" are the larval stages of free-living mites, generally belonging to the genus *Trombidium*, which are parasitic for a time in the skin of various animals, including man. Infection is from grass, etc., and only occurs out of doors. The mites tend to attack places where the garments fit tightly—under suspenders, belts, etc.—and are accordingly found most often on the lower limbs, although no part of the body is free from their attentions. The bite is intensely irritating, and causes a reddish swelling with a darker centre, which is the larval mite itself. An effective means of prevention is flowers of sulphur in the socks, etc. The best cure is a sulphur ointment locally. How to rid gardens of the pest is another matter, however, about which very little is known.

Income Tax

Interest on Bank Deposit

"W." writes: H.M. inspector of taxes wants to know how much interest I get from some hundreds *left* in bank as capital, the bank paying interest half-yearly, but not usually drawn on; I did not know that capital can be taxed.

*** It is true that it is income and not capital that is taxable, but the interest credited half-yearly by the bank is the income accruing from the capital deposited, and that interest is taxable whether it is actually drawn out or not. If the interest has not been assessed in the past the authorities have the right of assessing it for the previous six years.

Proportion of Residential Expenses

"D. M. M." owns a house the net annual value of which is £72, and sees practically all his patients in the professional portion, which consists of waiting room, consulting room, and secretary's room. The private portion of the house comprises basement, first and second floors, and attics. The inspector of taxes declines to allow a higher proportion than one-third of the total value as applicable to the professional portion.

*** We believe that where the "site" element of value is material it is a common view that the ground floor and basement represent two-thirds of the total letting value, and that is borne out to some extent by the old maximum income tax allowance of two-thirds. The usual basis adopted for medical practitioners in circumstances similar to those of our correspondent is one-half, and we think he should not be satisfied with less. On the other hand, that basis would leave a rental of £36 only as applicable to private accommodation (actually insufficient apparently, but adequate, perhaps, for a very small household), which hardly seems enough. In any case, "D. M. M." might give notice of appeal to the general or special commissioners with reasonable prospect of success, and could drop the appeal if, when the hearing was arranged, he found it too inconvenient to attend and argue his case.

Sickness and Accident Insurance

"P. P." is practising in partnership, and each partner is insured against sickness and accidents. Can they claim any deduction in respect of the payment of premiums?

*** No. Such insurances do not fall within the scope of the *life* assurance relief, and the premiums do not fall within the category of "money wholly and exclusively . . . expended for the purposes of the profession." If the premiums were paid out of the partnership bank account they would nevertheless be inadmissible, but equally any payments received by way of benefit would not be taxable receipts, even though they were paid into that account.

Earned Income Relief

"Y's" income from his practice is £900 per annum, out of which he pays £150 per annum as interest on loan. To what earned income relief is he entitled?

*** One-sixth of £750—that is, £150. It is true that he is assessed in respect of £900, but £150 of that amount is really the income of someone else, and the tax thereon is not ultimately borne by "Y" because it is deductible from the gross amount of interest payable.

LETTERS, NOTES, ETC.

Professional Classes Aid Council

The Professional Classes Aid Council, upon which the British Medical Association is represented by its Treasurer, Mr. Bishop Harman, records in its tenth annual report of 1930–31 that the amount spent in relief exceeded that of any previous year. The total number of applications received was 1,095, compared with 1,077 in 1929-30, direct financial assistance and help in kind being given to 285 families. The excellent policy of the council—namely, to help applicants to help themselves—aims not only to provide immediate pecuniary aid where necessary, but seeks to meet individual needs by referring inquirers to the society or fund most likely to furnish the requisite assistance. This advisory service forms an important part of the council's work, and was taken advantage of in no fewer than 387 cases. During the year forty-five training grants were paid to students and over seventy educational grants to boys and girls. The council also tries to assist those applicants who through age, illness, or other disability are no longer able to maintain themselves. While it is satisfactory to note that all this beneficent work has received financial support, notably a handsome donation of £7,500, the prospect for the present year is by no means as bright as it ought to be. It may not be generally known that the council acts as almoner for sums entrusted to it by donors who are interested in any particular case. All donations should be sent to the honorary treasurer, the Hon. George Colville, 251, Brompton Road, S.W.3.

Effect of Sunlight on Acne Vulgaris

Dr. H. G. CALWELL (East African Medical Service) writes from Tanganyika Territory: A few days ago I saw a severe case of acne vulgaris in a European in Dar es Salaam. He had suffered from the disease for several years, and had spent much of his substance on physicians without benefit. His back was widely scarred and showed much suppuration, but his face and chest were remarkably free. He told me that his chest had been as bad as his back, but that when he was up country he had gone about with his shirt open in front, and that the exposure to the sunshine had gradually caused the acne to disappear from his chest, while it went on as badly as ever on his back. Tropical sunshine is not to be had in England, but this experience suggests that perhaps artificial sunlight might be of use in the treatment of acne vulgaris.

Visits of Scientists to Russia

Dr. W. F. COOPER (Kingston Hill) writes from Russia: It is only fair to warn any scientific man—especially a medical man—who proposes to go on a scientific tour organized by the S.C.R. (Society for Cultural Relations), to make sure in London, before leaving, that he will see that class of subject which interests him, because he will be on a "conducted tour," during which many names are called out and he is hurried from place to place. This, though interesting, does not deal with any particular subject. So far I have seen nothing (according to programme) of medical interest. Though a medical man, starting with an assurance that I should see subjects of medical interest especially, I am allowed to see only plants and laboratories, and to meet men with long and unpronounceable names, who have no connexion with medicine. Possibly things may be better later, though we have no programme, so I cannot be sure. There was a programme, but it was not adhered to. If there are any, so-called, "eminent" men in the party, even though in the minority, their subjects are attended to. The wishes of the majority count for nothing, and it is an extremely arduous and rough tour. Beyond that, the tourist, if interested in seeing what the country is doing, will have a very interesting time indeed. So far as culture goes, he can get far more in London. The S.C.R. looks after the tourists extraordinarily well, and with extreme patience. "Intourists" give no assistance whatever, except to the "big men," and I can get no information from them about routes, costs, or anything.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 32, 33, 34, 35, 38, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 148.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

151 Corneal Clouding in Cranial Dysostosis

H. F. Helmholz and Ethel R. Harrington (*Amer. Journ. Dis. Child.*, April, 1931, p. 793) suggest that a seventh be added to the number of previously described syndromes with cranial dysostosis as the outstanding feature: these are: (1) oxycephaly (Virchow), (2) acrocephalosyndactylia (Apert), (3) congenital cleidocranial dysostosis (Marie and Sainton), (4) congenital craniofacial dysostosis (Crouzon), (5) dystrophia periostalis hyperplastica familiaris (Dzierzynsky), and (6) ocular hypertelorism (Grieg). The four cases recorded by the present authors occurred in a boy, aged 4½ years, and three girls, aged 17 months, 13 months, and 2½ years respectively. They presented the following features: uniform cloudiness of the cornea involving the deeper layers; no perceptible blood vessels; restricted movements of the joints of the extremities; short, thick, clawlike hands and feet, with limited extension; lumbar kyphosis; scaphocephaly; and mental retardation. The Wassermann reaction was negative in all four cases and the Pirquet reaction in three; it is not mentioned in the fourth. There was evidence of rickets in all, while in the third case an *x*-ray examination showed hydrocephalus with marked enlargement of the pituitary fossa and achondroplasia of the shoulders. The authors include in this group two cases described by Hurler, one by Putnam and Pelkan, and one by Jewesbury and Spence. They have no explanation to offer for the etiology of the cloudiness of the cornea.

152 Mental Complications of Insulin Treatment

E. Joltrain (*Bruxelles-Médical*, May 22nd, 1931, p. 868) has observed mental complications in several cases of diabetes or other diseases during treatment by insulin. He reports two typical cases of old-standing diabetes; one patient also suffered from pulmonary tuberculosis, the other having a weakly positive Wassermann reaction. In the first case insulin caused a return to a normal sugar metabolism, and the lung condition cleared up, but the patient lost his memory, became very confused, alternately wept and laughed, was constantly on the move, and could not sleep. On stopping the insulin the patient's mind returned to normal. This sequence of events was repeated when insulin was given again, until it was found possible to place the patient on an insulin-free diet, when he returned to normal. Similar, but not quite so marked, complications arose in a second case, which is also described in detail. There seemed to be some alternation between the physical and mental nervous signs, and the author asks whether the existence of some mental equivalent of hypoglycaemia can be presumed.

153 Perihilar Pulmonary Tuberculosis

Pulmonary skiagraphy has modified the classical opinion that the primary focus of tuberculosis is usually apical, and K. Faber (*Acta Med. Scand.*, June 12th, 1931, p. 403) confirms the observations of several writers that perihilar infection is more general among young adults than has been hitherto believed. Some believe that the majority of cases commence as a perihilar lymphadenitis, with secondary pulmonary invasion. Faber describes eight cases; seven patients were women, and all but two of these were under the age of 25. The eighth patient was a man, aged 23. In seven cases the expectoration was very scanty, usually only a singie clot, but tubercle bacilli were found in all specimens; one patient had no expectoration. Authors agree that prognosis is relatively good. In the majority, under suitable treatment, the tuberculous process becomes inactive and the patients are free from symptoms. Faber confirms the experience of others that this lesion is more common in young persons, and erroneous conclusions may be caused by vagueness of symptoms, the scantiness of the expectoration, and negative auscultation findings. Diagnosis depends on skiagraphy, and is usually simple, though the appearance sometimes suggests a neoplasm. In the majority of cases shadows radiating from the hilus are characteristic. Auscultation is uncertain, since the physical signs are indefinite or absent owing to the depth of the lesion. More often, dullness, rales, and respiratory changes are found in the axillary and infrascapular regions. Apical rales may be heard, though skiagrams of these regions are negative. The usual treatment is artificial pneumothorax, and the results are usually good since pleural adhesions are rare. One objection to this procedure is that hilar lesions are often bilateral. Faber treats all patients with sanocrysin, and only later performs pneumothorax, even when the lesion is unilateral. All the patients reported received sanocrysin treatment only, and in six instances the results were good. Faber thinks that immediate pneumothorax might have saved the patient who died, since she had a large unilateral perihilar cavity.

154 Haemolytic Jaundice

J. Neuburger (*Deut. med. Woch.*, June 5th, 1931, p. 969) records the results of treatment in two cases of haemolytic jaundice. In one of these, paraesthesiae, achylia gastrica, and megalocytosis were also present, but the presence of a still more marked microcytosis, great increase of bilirubin in the blood, and increased fragility indicated that acholuric jaundice was the correct diagnosis. In both patients the exhibition of liver, liver extract, and powdered stomach was entirely without effect on either the anaemia or the haemolysis, although the megalocytosis was improved in the atypical case. Iron, on the other hand, influenced the anaemia favourably, though having no effect on the haemolysis. Neuburger concludes that the symptoms of acholuric jaundice are very resistant to medical treatment, and that the mechanism of the haemolysis is different from that in pernicious anaemia.

Surgery

155 Pneumatic Rupture of the Intestinal Canal

C. A. V. Burt (*Arch. of Surg.*, June, 1931, p. 875) describes pneumatic rupture of the intestinal canal as an uncommon condition due to the introduction of air under pressure into the oral cavity or the rectum. Forty cases have been already reported and a further two are described in detail. The cause in nearly every case has been due to a practical joke on the part of a fellow worker who has directed the nozzle of a compressed air machine towards the injured patient. Occasionally the bowel has been accidentally ruptured by a physician when using a pneumatic sigmoidoscope. The sigmoid is the viscus most frequently ruptured, while the rectum supports the greatest pressure; a higher pressure is required to rupture portions of the alimentary canal in children than in adults. It was found experimentally that the average pressure required to perforate the various parts of the intestinal tract was 4.07 lb. per square inch. The two outer coats of the colon generally rupture along the longitudinal bands; this is followed by herniation and perforation of the mucosa on the anti-mesenteric surface. In 50 per cent. of cases of rupture of the small intestine, all the layers perforated simultaneously on the anti-mesenteric surface with slight laceration of the outer two coats. In the remaining 50 per cent. of specimens, mesenteric ruptures occurred. The symptoms usually include very severe colicky pain in the lower part of the abdomen, difficulty in breathing, enormous distension of the abdomen, and obliteration of abdominal dullness with marked hyperresonance. The patient generally shows a marked degree of shock with cold, clammy skin; cyanosis, nausea, and

vomiting are usually present. Treatment for the abdominal condition is immediate operation with preliminary paracentesis abdominis in cases of marked distension, to release any air and relieve the pressure on the diaphragm. In cases where only small damage has been done to the serous and muscular coats, this may easily be repaired, but when the injury is more serious, resection of the damaged portions and the establishment of a colostomy are indicated. The prognosis is grave, the general mortality being 56.81 per cent., the operative mortality 44.82 per cent., and the non-operative mortality 80 per cent. If an operation is performed within six hours after the injury, the chances of recovery are greater than if a longer time elapses.

156 Riedel's Disease

M. PRATI (*Arch. Ital. di Chir.*, May, 1931, p. 93), who records two illustrative cases in women aged 51 and 56, states that the characteristic features of Riedel's disease are: (1) the development of a process in the thyroid gland; (2) a secondary but early spread of the process from the confines of the glands, and invasion of the neighbouring tissues and organs of the neck; and (3) the histological and clinical appearance of a chronic inflammation with a well-marked tendency to connective tissue sclerosis which gives the affected tissues their peculiar hardness. Very little is known as to the etiology of the disease. In some cases a syphilitic or tuberculous origin has seemed likely. The symptoms are mainly due to the pressure exercised by the cervical mass on the organs and vasculo-nervous structures in the neck. The course of the disease is usually fairly rapid. Without any premonitory symptoms there arises in the antero-lateral region of the neck an extremely hard swelling, the thyroid origin of which is at first easily demonstrable. It is at first readily movable on the skin and deeper structures, but rapidly becomes adherent to the trachea, oesophagus, vasculo-nervous tissues, and muscles. The neck becomes rigid and the larynx immovable. Severe functional disturbances, especially affecting the respiratory system, develop very early, and sometimes end in attacks of asphyxia. Pressure on the recurrent laryngeal nerve interferes with speech. Occasionally the pain radiates to the neck, shoulder, and ear. Removal of a small part of the growth or a simple incision may often be sufficient to cause a gradual or rapid disappearance of the lesion. In some cases resolution may be spontaneous or result from the application of *x* rays or the institution of antisyphilitic treatment. Both Prati's patients recovered rapidly after removal of small pieces of the growth.

157 Primary Carcinoma of Ureter

L. CAPORALE (*Urol. and Cut. Rev.*, June, 1931, p. 341), who records an illustrative case, states that primary carcinoma of the ureter is a rare condition of which only fifty-one cases have hitherto been recorded, the first having been published by Rayer in 1841. The condition occurs with equal frequency in both sexes. The age ranges from 35 to 89, 60 per cent. of the cases occurring after the fiftieth year. The most frequent symptoms are pain in the affected flank, radiating along the course of the ureter; frequent haematuria, which may be either continuous or intermittent; urinary symptoms such as dysuria, pollakiuria, or polyuria; and general symptoms, such as anaemia, vomiting, and emaciation. In most cases the growth produces hydronephrosis. The diagnosis is not always easy, and in only sixteen of the reported cases was it made before operation or necropsy. Urological examination in the form of cystoscopy, ureteral catheterization, and retrograde as well as intravenous pyelography is of aid in reaching a correct diagnosis. The prognosis is extremely grave; 60 per cent. of the reported patients died without subjection to treatment by nephro-ureterectomy. Caporale's patient was a woman, aged 75, whose symptoms were intermittent haematuria, vesical tenesmus, and pollakiuria; a diagnosis of papilloma of the ureter was made after bilateral ureteral catheterization and intravenous pyelography. At operation a growth was found at the lower end of the left ureter, and the kidney showed a condition of atrophic hydronephrosis. Nephro-ureterectomy was performed and the patient made a rapid recovery. Examination of the growth showed it to be a carcinoma of compound pavement epithelium, in part papillomatous. A later recurrence in the bladder was destroyed completely by electro-coagulation.

Therapeutics

158 Intracardiac Adrenaline in Neonatal Asphyxia

H. HOFMANN (*Zentralbl. f. Gynäk.*, June 20th, 1931, p. 1977) states that intracardiac injections of adrenaline for the resuscitation of the newborn with white asphyxia was first recommended in 1919 by Vogt. In 1925 von Wachenfeld recorded 25 cases with two successes; one was a case of spontaneous birth in which the delivery of the shoulders lasted five minutes, while the other was a case of prolapse of the umbilical cord in which version was performed. Laviano, in 1927, reported 6 cases with four successes. Hofmann now reports 26 cases from the German University Women's Clinic at Prague, in two of which the results were favourable, though only one patient actually recovered. The first case was one in which high forceps had been applied owing to prolapse of the umbilical cord. No pulsation could be felt in the cord, but feeble heart beats could be detected. An intracardiac injection of 1 mg. of adrenaline was given and the heart began to beat vigorously. After about one hour's efforts at resuscitation the child began to cry, and the mother and child were discharged in good condition twelve days after delivery. In the other case, which was one of spontaneous birth, 0.06 mg. of adrenaline was injected, and the heart began to beat vigorously, but another attack of asphyxia occurred within an hour and death ensued. At the necropsy laceration of the tentorium was found to be the cause of death.

159 Potassium Thiocyanate in Essential Hypertension

D. AYMAN (*Journ. Amer. Med. Assoc.*, May 30th, 1931, p. 1852) insists that there is no clear evidence in medical literature that the exhibition of the thiocyanates has any real clinical value in essential hypertension. They cause unpleasant reactions in large doses, and are ineffective in small ones. Ayman gives details of a series of patients so treated, and concludes that potassium thiocyanate is valueless in the majority of hypertensive patients who have narrowed retinal arterioles, cardiac enlargement, or slight renal involvement, while its admittedly hypotensive effect is almost always associated with distressing reactions. The hypotensive and toxic sequels of treatment always occur simultaneously, and are produced whether large doses are given for short periods or small doses are spread over a long time. The patients usually complain first of drowsiness, general weakness, and retarding of physical and mental activities. In some cases there were gastro-intestinal symptoms such as anorexia, nausea, cramps, and diarrhoea. While the gastro-intestinal manifestations ceased within a week after stopping the drug, the others persisted for two to six weeks. Ayman concludes that in view of the well-established results, in these cases, of exhibiting less toxic sedatives, such as the bromides, further clinical study and employment of the thiocyanates should be limited to the purely functional and early stages of the disease. Clinically demonstrable arteriolar sclerosis is a contraindication to their use.

160 Tetrachlorethylene as an Anthelmintic

Confirming the results obtained in animal experiments and human subjects by various investigators, C. GARIN, J. ROUSSET, and B. GONTHIER (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, June 15th, 1931, p. 1003) have found tetrachlorethylene an excellent anthelmintic against ankylostoma, ascarides, tricocephala, and certain taeniæ, and summarize their results in 358 cases. Cure ensued in 247 out of 270 patients (91.5 per cent.) whose faeces were microscopically controlled; in 209 (77.4 per cent.) only

ne treatment was necessary. Tetrachlorethylene is a iquid of 1.6595 density, boiling at 121° C. It has been ised chiefly as a fat solvent. The drug is administered n 1 gram capsules for three consecutive days in doses of ;, 4, and 5 grams on each day respectively. In debiiitated ases the authors advise that only 3 grams should be given ach day. The capsules are taken in the morning, one by ne at intervals of an hour. On the third day, about hree hours after taking the last capsule, a saline purge 40 grams of sodium sulphate) should be administered. During the treatment the patients should be kept at bsolute rest ; they must avoid alcoholic drinks, and take arge quantities of milk. No ill effects have been noted luring treatment ; some patients have felt a transitory ensation of unsteadiness and vertigo immediately after aking the capsules. Though the drug is eliminated by he kidney, albuminuria has never been noted. The rine, which gives an orange-red colour with nitric acid, should be tested daily during treatment, three or four ours after ingestion of the capsules.

Dermatology

161 Sugar Intolerance in Certain Skin Diseases

. G. CAMPBELL (*Brit. Journ. Derm. and Syph.*, June, 31, p. 297) has previously suggested, from a review of cases, that sugar intolerance might be an etiological ctor in some dermatoses. An analysis of 132 further ises of various skin diseases in which sugar tolerance eterminations were made is now presented. Positive sults were obtained in 77 per cent. of the patients. ching, more annoying and intense than usual, was the ost constant symptom, and a tendency to chapping of ands in cold weather was found to be very suggestive f sugar intolerance. It has long been known that the pro-nged contact of sugar with the skin can cause a dermat-is. Usher and Rabinovitch have shown that the sweat i persons exhibiting sugar intolerance contains an ab-ormal amount of sugar ; this may account for conditions uch as seborrhoeic eczema, in which the disease appears n the parts of the body frequently bathed in sweat, and he high blood sugar may be the direct cause of the con-ition. While not advocating the abandonment of ordinary herapeutic methods, Campbell claims that, in cases of ugar intolerance, a diet which keeps the blood sugar within the normal limits is of great aid in successful reatment, and may indeed be necessary.

162 Infantile Eczema

M. and MME H. MONTLAUR (*Ann. de Derm. et de Syph.*, May, 1931, p. 513) report a study of eczema of nurslings, based on 54 cases. In 53 the affection commenced on the buttocks between the ninth and fortieth (usually the fifteenth) day of life ; in the remaining case it originated in the retro-auricular fold at the age of 2 months. Thirty of these babies were solely breast-fed ; eleven received mixed feedings, and thirteen at first were on artificial diets. The disease, which commenced as a slight erythema on the buttocks, spread more or less rapidly to the adjoining parts, until almost the whole of the postero-inferior portion of the body was involved. As the condition progressed, an eczematous eruption (the eczematide of Darier), associated with intertrigo, appeared on the upper part of the trunk. A more or less intense pruritus was evidently also present. The dermatosis was therefore of mixed type: intertrigo and eczema of the newborn (infantile dermatitis) of the lower part of the body, and parakeratosis of the upper portion. The inflammatory phenomena gradually subsided, leaving a condition of seborrhoeic eczema. Notes are given on the bacteriology and chemistry of the disease. Enterococci were isolated both from the epidermal scales and faeces, and it is suggested that the malady is an enterococcal epidermitis. An anti-enterococcal vaccine has given unexpectedly good results, and has therefore been employed, without local measures, as the sole method of treatment.

163 Disseminated Parapsoriasis

PILLON (*Bull. Soc. Franç. de Derm. et de Syph.*, May, 1931, p. 711) records a case of a peculiar generalized pigmented dermatitis, which, according to the patient, originated four years previously in an attack of furunculosis. The actual present disease commenced as a red mark, as large as a 2-franc piece, on the right forearm. This remained isolated for eighteen months ; other similar lesions then appeared slowly over the whole of the body, and the patient developed a peculiar spotted appearance. The eruption was not so marked on the face. During the evolution of the disease, three marked exacerbations occurred after a year, eighteen months, and twenty months. The lesions, at first red, rapidly became brown, and were of various dimensions. Pruritus, disturbances of sensation, adenopathies, and splenic hypertrophy were absent. The disease appeared to be absolutely stable, and the pigmented areas remained unchanged. On the back of the hands there were some lesions resembling lichen planus ; on the elbows and knees some patches simulating psoriasis were present. In consultation with Nicolas, a diagnosis of parapsoriasis was made by a process of elimination ; this was confirmed by a subsequent biopsy. Since bismuth produces good effects in tuberculides, and particularly in lupus erythematosus, Pillon tried this treatment in the present case. Cure was obtained by six intramuscular injections of bismuth hydroxide. A recurrence which occurred some months later yielded to two similar injections.

164 The Pyrogallic Acid Treatment of Lupus Vulgaris

F. DIETEL (*Derm. Woch.*, May 30th, 1931, p. 891) prefers 10 to 20 per cent. pyrogallic ointment to other caustics in the treatment of lupus vulgaris and considers the Gerson-Sauerbruch-Herrmannsdorfer diet a valuable adjuvant. In applying the ointment the surrounding skin is protected with a layer of zinc paste or Lassar's paste, and the pyrogallic ointment is covered with some waterproof substance to enhance the effect, except in areas such as the back of the hand, where there is risk of damage to important structures if the caustic penetrates much below the surface. Owing to the risk of toxic symptoms from absorption the maximum area treated at one time is the size of the palm of the hand. The treatment is repeated daily for four to six days ; if it is followed by an application of 5 per cent. panthesin balsam (a novocain derivative) for a few days, and after this an indifferent ointment is applied, the severe pain associated with the use of caustics is to a large extent avoided. Three or four such courses of pyrogallic ointment are generally required, and, finally, in order to accelerate the growth of epithelium and facilitate satisfactory scarring, a dose of x rays is advocated.

Obstetrics and Gynaecology

165 Treatment of Puerperal Sepsis

E. FAUVET (*Zentralbl. f. Gynäk.*, May 9th, 1931, p. 1574), discussing the treatment of puerperal sepsis, remarks that injections of metallic or tinctorial bactericidal substances are of little or no use, and may possibly be harmful; while non-specific protein therapy may do harm by overstimulating the defence mechanisms. Of antitoxin and serum treatments the injection of serum from a convalescent patient is the most useful. During the past two years at the Leipzig Universitäts-Frauenklinik, the most important treatment after early appearance of signs of severe puerperal sepsis has consisted in the continuous injection into an antecubital vein of 4 per cent dextrose dissolved in normal saline solution, 1½ litres are given in twenty-four hours, and the injection is sometimes repeated several times. This treatment, which was recommended by Küstner and Kirstein, has the effects of replacing water loss and of supplying a readily assimilated and katabolized foodstuff which also stimulates the heart and circulation. Adrenaline, pituitary extract, a cardiac tonic, or insulin

may be added to the infusion, in some cases considerable amounts of alcohol are given by the mouth Fauvet is satisfied that a great improvement in the mortality rate in severe puerperal sepsis has followed the introduction of continuous dextrose saline infusion.

166 Toxaemia in Early Pregnancy

P Mauriac (*Journ de Med de Bordeaux*, June 20th, 1931, p 539) recalls the distinction emphasized by G Fieux between toxaemia in early and late pregnancy, indicating a difference of origin In the case of this condition during the first four months of pregnancy the toxaemia can be related to the changes in the uterus following the implantation of the ovum, and it has been stated that the blood contains a specific antibody which disappears entirely in later pregnancy Mauriac believes that toxaemia in early pregnancy is closely concerned with the commencing development of the placenta, and with the operation of the placental hormone more particularly He emphasizes the importance of investigating more closely and systematically the physiology and pathology of the placenta in its earlier stages Recently, light has been thrown on the physiological changes at this time by the researches of Aschheim and Zondek, and this line of research should be followed further.

167 Ovarian Cysts and Pregnancy

Delannoy and L Gerniz (*Bull Soc d'Obstét et de Gynecol de Paris*, May, 1931, p 355) record a case of an enormous ovarian cyst occurring during pregnancy, for the following reasons the rarity of such a large ovarian cyst, the unusual coexistence of similar cysts with a normal pregnancy and puerperium, and the influence of gestation on ovarian cysts In this case, the pregnancy, if it had not caused the cystic formation, had evidently increased its volume This is contrary to the opinion of some authorities that pregnancy does not influence the development of ovarian cysts The cyst, which was apparently unilocular, and contained 18 litres of fluid, was excised with excellent results about six months after delivery The following procedures are recommended in pregnancies complicated by these cysts If the presence of the cyst is recognized during the first half of pregnancy, it should be excised as soon as possible, morphine administration diminishing the risk of abortion, if diagnosed during the second half expectant measures should be adopted, provided that the patient can be closely watched Delivery generally occurs spontaneously It is wise to wait for six weeks to two months after the labour before operating, since the risks of ovariotomy are much greater during the puerperium Should serious complications arise, such as compression, or torsion, or rupture of the cyst, operative intervention should be immediate, whatever the stage of pregnancy

Pathology

168 Sodium Thiosulphate Excretion in Pregnancy

A Boiliger and M S S Earlam (*Med Journ of Australia*, April 11th, 1931, p 427) estimated the excretion of sodium thiosulphate intravenously injected in a series of non pregnant and pregnant women, in order to ascertain whether more rapid or lowered excretion observed in pregnant animals was present in the human subject and, if so, its extent and significance The patients remained in hospital from about two months before and for one month following confinement, and were suffering from venereal disease, but the depressions noted in pregnancy, and not to regarded as primarily due to pregnancy, were non-pregnant patients the associated infection of papilloma. The thiosulphate excretion were the excretion fell within the normal limits except in a small group of complicated cases In nearly all instances the percentage of thiosulphate excreted in a catheterized specimen was found to be less than the normal during the first part of pregnancy, and in many cases during the puerperium.

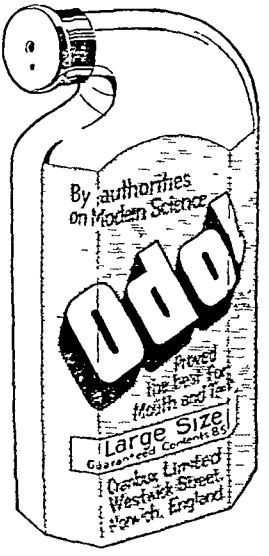
According to the extent of the lowering patients were classified in two main groups (1) those in which it was not extensive and was of short duration, and (2) those in which it was marked and prolonged, continuing in some instances as long as a year after confinement In none of the patients was there any clinical evidence of either renal insufficiency or of toxaemia

169 Cell Growth in Relation to Cancer

G W Crile (*Amer Journ Surg*, May, 1931, p 217) reports research into the formation of "autosynthetic" cells, with special reference to fertilization, the production and growth of cancer cells, and the etiology of fatty degeneration The lipoids and proteins of the brain of freshly killed normal animals were extracted and reduced to ash By mixing together the brain lipoids proteins and a solution of the brain ash, or of the electrolytes contained in the brain, the process of fertilization in nature by the union of the spermatozoon and ovum was roughly imitated Observation of this mixture revealed cell like forms, which multiplied sometimes by budding and sometimes by direct division Crile states that these autosynthetic cells were nucleated, absorbed intravital stains, consumed oxygen, gave off carbon dioxide and produced urea Control experiments indicated that the brain lipoid was unique in being able to collaborate with the electrolytes in organizing the proteins of any organ The autosynthetic cells were not formed, however, when the brains of dogs which had died from distemper were employed, nor in the case of those from rabbits which had died from exhaustion due to insomnia The significance of these findings is discussed with special reference to cancer formation in the presence of changes in the hydrogen-ion concentration It is concluded that continued alteration in the *p*H may be a strong factor in reducing the highly differentiated molecules of the normal cell to a lower level—that of growth only—or in other words, to the cancer level The conception that cancer cells have a higher dynamic potency than ordinary tissue cells is contested by Crile, who suggests that their success in invading the body is due to unpreparedness for growth competition on the part of the tissues and organs rather than to the severity of the attack The comparison between the autosynthetic cell and the cancer cell is held by the author to throw very considerable light on the whole question of malignant transformation.

170 Vibrionic Diarrhoea in Cattle

F S Jones and R B Little (*Journ Exper Med* June 1st, 1931, p 835) have studied a disease of cattle which occurs in epidemic form during the autumn and winter months in certain parts of the United States It is characterized by the passage of dark brown or blackish brown liquid faeces, often containing mucus and blood, and is sometimes known as winter dysentery and sometimes as black scours The mortality appears to be low, but the milk yield is seriously affected both during and after the attack Experimental feeding of calves with faeces from spontaneous cases gave rise to a similar but milder disease Cultures made from the inflamed jejunum yielded vibrios which, on being fed in pure culture to fresh calves sometimes produced an enteritis similar to that occurring in the natural disease In another paper (ibid, p 849) the authors describe a similar infection of calves Animals two weeks or more old are affected, they are unhealthy in appearance, and often have a chronic diarrhoea accompanied by the passage of faeces varying from clay to dark brown in colour, with sometimes blood and mucus The disease is apparently most common in the autumn Vibrios were recovered from the mucosa of the upper jejunum and occasionally from the liver One strain which had been recently isolated produced severe enteritis when fed to a calf, and the organisms were recovered from the jejunum In a third paper (ibid, p 859) F S Jones, M Orcutt, and R B Little describe the characters of the vibrios with particular reference to *Vibrio fetus* to which they are closely related They propose the name of *Vibrio jejuni* for the new organism.



THE 6 REQUIREMENTS OF THE PERFECT MOUTHWASH & GARGLE

★ Requirement No. 1

The first essential of the perfect hygienic mouthwash is that it must be absolutely innocuous, and in this respect Odol is ideal, for while it is antiseptic in its effect, it is perfectly harmless to the mucous membrane, to the teeth and to the whole organism. Odol is definitely non-caustic; it does not destroy the lime salts, and it is non-poisonous. If swallowed accidentally while gargling, no ill-effect will result. Yet, though absolutely safe, Odol has a Rideal Walker co-efficient of 0·6.

The Six Requirements

★1 It must be absolutely harmless.
2 It must be absolutely non-irritant to the mucous membrane of the mouth.
3 It must be definitely antiseptic.
4 It must be neutral in reaction.
5 It must be deodorising and refreshing.
6 It must be agreeable to the taste.

All Six Requirements are fulfilled by

Odol

MOUTHWASH

Samples and literature will be gladly sent to members of the Medical Profession on request to Cranbur Limited of Norwich.

BRITISH MADE BY BRITISH LABOUR. FINANCED BY BRITISH CAPITAL.

The Collection of Overdue Accounts

WITHOUT OFFENCE

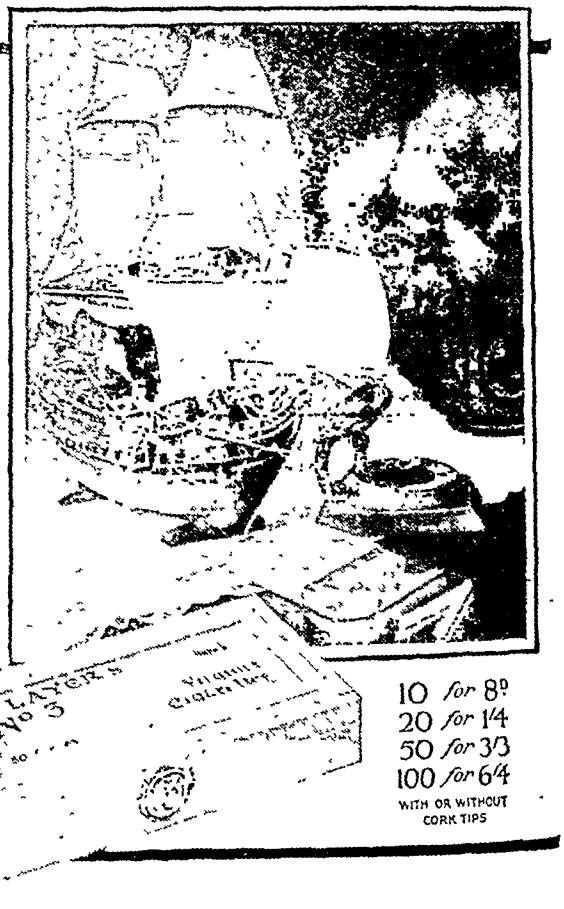
Your visiting card marked "B" in an envelope will bring our Prospectus.

THE BRITISH MEDICAL PROTECTION SOCIETY

(B.M.P.S. Ltd.) Established 1891.

26, Langham Street, Portland Place, London, W.1

Telephones: Langham 1411-1412. Secretary: N. Rutherford Watson.



The slogan "WITHOUT OFFENCE" sounds absurd in connection with the collection of bad debts: but if you were to read the innumerable excuses made to us by Doctors, you would realise, as we did 40 odd years ago, that our system of dealing with these cases is the finest in the Kingdom and our method produces the Best Results.

All Medical Institutions and Nursing Homes are included in our scope.

This is a large country house, with beautiful grounds and park, five miles from Sheffield. Station: Grange Lane, L. & N.E. Railway, Sheffield. Telephone: No 40030 Ecclesfield. Resident Physician: GILBERT E. MOULD, L.R.C.P., M.R.C.S.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS.

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

F.R.C.S.EDINBURGH.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.
¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

Royal College of Physicians of EDINBURGH

KIRK DUNCANSON FELLOWSHIP FOR MEDICAL RESEARCH

In accordance with the bequest by Mrs. ISABELLA KIRK DUNCANSON to commemorate the late Dr. J. J. KIRK DUNCANSON, the Council of the Royal College of Physicians of Edinburgh will award the Kirk Duncanson Research Fellowship in October, 1931. The Fellowship will be awarded annually for a period of one year. It may be renewed to the same beneficiary for two additional periods of one year each. The emolument will be upwards of £150 for the first year, about £250 for the second year, and about £350 for the third year. In recognition of Dr. Kirk Duncanson's interest in the Diseases of the Ear, Nose, and Throat, in making this first award special consideration will be given to the claims of candidates who propose to devote themselves to that branch of Medicine. Applications and recommendations with particulars of the special line of research contemplated, and of the place where the investigations are to be conducted, should be in the hands of the Secretary of the College by October 15th.

British Medical Association

APPOINTMENT OF SCOTTISH MEDICAL SECRETARY

The Council of the British Medical Association is prepared to receive applications from registered medical practitioners for the appointment of Scottish Medical Secretary. He will be required to live in Edinburgh and to give his whole time to the duties of his office. Duties to commence as arranged but not earlier than January 1st, 1932, and the appointment to be subject to six months' notice on either side.

Salary £950 rising to £1,250 by annual instalments of £50, subject to deductions for superannuation.

Applications stating experience and age with not more than three recent testimonials should be received by the Medical Secretary, British Medical Association, Tavistock Square, W.C.1, not later than by first post October 1st, 1931.

Canvassing not allowed.

ALFRED COX,
Medical Secretary.

Wilts County Council.

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL INSPECTOR

The Wilts County Council invite applications for the appointment of an Assistant County Medical Officer of Health and Assistant School Medical Inspector. Applicants must be fully qualified Medical Practitioners and must hold a Diploma in Public Health, or an equivalent qualification.

The salary will be £600 per annum rising by annual increments of £25 to a maximum of £750 per annum, and will be subject to a deduction of 5 per cent. for superannuation under the Local Government and Other Officers Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination. Travelling allowance for own motor car in accordance with County scale.

The officer appointed will be required to reside in any centre in Wiltshire as may be decided by the Committee, to devote his whole time to the duties of the office and to act under the direction and control of the County Medical Officer of Health, who is also School Medical Officer. The duties of the post will be chiefly concerned with the School Medical Service but a proportion of the officer's time will be devoted to the Public Health work of the County and work under the Mental Deficiency Acts. The appointment will be determinable by three months' notice on either side.

Applications on form to be obtained from the undersigned, together with copies of not more than three recent testimonials and enclosed in envelope marked "Assistant Medical Officer," to be lodged with the undersigned not later than the first post on Monday, August 31st.

Canvassing, either directly or indirectly, is strictly prohibited, and will be regarded as a disqualification.

County Offices,
Trowbridge.

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

(6) MIDLANDS.—Outdoor £400 p.a.

Full Schedule of Terms and Conditions will be forwarded on application.

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is Essential to Sustain the patient without irritating the Digestive Organs, the Ease of Assimilation and Power of Valentine's Meat-Juice to Restore and Strengthen has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

BABY'S ONLY FOOD FROM BIRTH TO 2½ YEARS

ROSARIO
18th May, 1931

To Messrs. Cow & Gate, Ltd.
Guildford, ENGLAND

Dear Sirs,

Until two months ago Baby has been existing only on Cow & Gate milk, as she refused to take any solid food. Everyone told me she ought to be eating other food, but evidently what she did have made up for it, and everyone remarked how bonny she was and what strong bones and muscles she had. We would not be without it for worlds and thoroughly recommend it to all our friends.

She still has three breakfast-cups a day—one on getting up in the morning, one at siesta time and one on going to bed—and thoroughly enjoys it and has never had one minute's discomfort, even during our extremely hot summer days. She is very intelligent and bright.

I remain, Yours very truly Hilda J. Taylor.

We make no apology for publishing this mother's letter in the Professional Press—because we feel that it will be of clinical interest.

Name:
ESME HILDA TAYLOR
Born:
27th August, 1928
Photo Taken:
10th May, 1931
Age:
2 years 8½ months
Weight:
33 lbs.
Height:
3 ft. 1 inch

Cow & Gate Milk Food

"Cow's milk made safe and suitable for baby"
it is said, has saved more baby lives than any other preparation in the world

NUMOL

THE FOOD OF HEALTH

BONE FORMATION

Recently a doctor practising in a North of England town gave us particulars of a case of a man of 63 years of age who had suffered from a complete fracture of the lower jaw. He was under treatment for about seven weeks and, although he was X-rayed several times, there was no evidence of the slightest improvement and no new bone formation at all. The patient was, at the outset, in a poor physical state, and had now become in a very low condition indeed.

At this stage the doctor prescribed NUMOL, and within a week there was real evidence of progress: the NUMOL treatment was continued, and the patient made a complete recovery—not merely did the fracture of the jaw clear up and the new bone become formed, but the patient's general condition was enormously improved.

Doctors who are not already prescribing NUMOL in bone cases are asked to give it a trial, and a sample will be sent on receipt of a card.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-

SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.

5, WIGMORE STREET, LONDON. W. I.

AN SANDO

Real comfort rests in Elasticity

ELASTOPLAST BANDAGES

already the proved cure for Varicose Ulcer, are also ideal for compression and support in cases of Varicose Veins, Sprains, Strains, Dislocations, after treatment of fractures and for all Surgical and Orthopaedic work.

Elastoplast is the only elastic plaster bandage possessing the correct degree of elasticity to ensure perfect compression and support.

ELASTOPLAST DRESSINGS

combine the elastic plaster with antiseptic pads of gauze and lint. Instantly applied they mould readily to the shape, are ventilated, pliable, neat and healing. They need not be removed when washing, and can be left in situ until the wound is healed—or examined at intervals if necessary.

Elastoplast dispenses with ordinary bandaging—will save you much valuable time, and reduce your dressing accounts.

Elastoplast

Patent No 253 527

BRITISH MADE.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P O value 2/6 (Overseas postage extra) by the manufacturers:

Also

VISCOPASTE BANDAGES

(Unna Paste Type). A valuable adjunct to the after-treatment of Varicose Ulcer.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

SMOKE! Soot! Fogs! Shutting out the sun. Destroying health. Damaging property. Delaying transport . . . . . What makes our skies so filthy? *Coal Smoke* . . . . . belching from the chimneys of our factories and homes. You can help to fight this evil, to clean the sky, to let in the sun. Use Gas, the smokeless fuel. With the great progress of gas the smoke curse is waning. In the last 15 years in London, for instance, the number of gas appliances in use has more than doubled; the sootfall has been more than halved. Help to abolish the smoke nuisance! Use Gas more!

X-RAY YOUR PATIENTS

wherever they are——
at surprisingly low cost

Negatives developed within 10 minutes—perfect results assured

THE METHOD and its results

The apparatus is assembled at the patient's bedside and one small line, carrying both the electric and signal wires, is led from the car through any convenient window. The driver on the car then supplies current as and when required by the radiographer.

Immediately the exposures are made the films are developed on the car, and the finished negatives are ready to be seen within about ten minutes.

A Potter-Bucky diaphragm and fluorescent screen are also carried. Great penetration of any part of the body is ensured, and the definition of the negative is rendered equal to that of any permanently installed apparatus.

VERY often it is inadvisable to move a patient for an X-ray examination. More often still the advantages of such an examination cannot be enjoyed because of the difficulties involved. To-day in such cases as these X-ray examinations can equally well be made at the patient's bedside.

Powerful portable apparatus is available day and night for service anywhere—under the control of experienced radiographers.

Within forty minutes of arriving at a house the negatives are ready for inspection—the films being developed on the car, which is fitted up as a dark room.

The taking of the radiographs can be conducted throughout under the supervision of the medical practitioner concerned.

Seven years' experience in X-ray car service has produced a simplicity of service and a speed of working which constitute a unique service to the medical profession—making possible the more constant use of radiography at surprisingly low prices.

Any medical practitioner is invited to study the results of this method of radiography at any time, on application to the Company.

Full details, in the form of an interesting descriptive booklet, will gladly be sent on request.

Write, wire or telephone to-day——

Special attention for urgent calls

The charges are graded according to the distance travelled from London—the basic charge within 10 miles of London being only four guineas, and one guinea for each subsequent radiograph at the same visit

Special terms for hospitals

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me";* without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in. × 15in. × 11in.

Salt and Son Ltd.

SALT'S MATERNITY BELT-CORSET

From our own experience (and confirmed by the opinion of many Medical Men) we are convinced that this Corset is vastly superior to anything previously made, for the following reasons:—

1. It has an elastic front, with lacings at each side, which allows the necessary expansion.
2. It has a deep back, closed and firmly boned, which gives great support.
3. It is not carried above the waist in front, thus avoiding pressure on the bust.
4. It has a lower abdominal support, which provides maximum uplift.
5. It gives great comfort to the wearer by reason of its simplicity and elasticity.
6. It is anatomically correct throughout.

As in the case with all Salt's Special Appliances, this Corset is supplied in varying qualities to suit the means of all, and is made ONLY to the requirements of each individual case.

Catalogues sent on request.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally.

In all the various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose: One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England 12/6 per pound.

Introduced and Prepared only by

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte St., London, E.C.2.

STANIFORM
Regd. BRAND. Trade Mark.
METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contraindicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment."

"Festering wound on left heel—when first seen was about the size of a shilling, with a good deal of pus. Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

TABLETS "B.S.C."

TRADE MARK

(Bile Salt Compound)

For Constipation, Intestinal Toxæmia, Hepatic Deficiency, Gall Stones and allied conditions.

Tablets "B. S. C." contain active pancreatic extract and bile acids, extract of duodenal mucous membrane and a proportion of ipecacuanha and emodin. Their administration stimulates the flow of glandular secretions which complete the digestive processes; the bile salts emulsify and detoxicate the food residue, while the emodin and ipecacuanha exert a tonic effect on the visceral musculature, particularly the colon, thus stimulating peristalsis.

Tablets "B. S. C." are of particular value in the treatment of constipation, hepatic disorders and the toxæmias arising from stasis. In conjunction with hexamine, they are of distinct benefit in the treatment of gall-stones and cholecystitis.

Supplied in bottles containing 40, 80, 160 and 500 at 2/6, 4/6, 8/6 and 20/-

Gastric Disturbances

An ACID Liq. Pepsin et Bismuth Co.

LIQ. GASTRORUBE

℞ Pepsin (O.S. & Co. 1-3000), gr. 1; Tinct. Nuc. Vom., m. 5; Ac. Hydrocyan. Dil. B.P., m. 2; Bismuth (equal B.P. Liquor, ad dr. 1).

Special attention is directed to the fact that this solution is acid, thereby retaining the full proteolytic activity of the Pepsin. The chemical difficulties of producing an acid solution of Bismuth have been successfully overcome, and the therapeutic advantages of prescribing LIQ. GASTRORUBE are obvious.

SAMPLES AND FURTHER PARTICULARS ON REQUEST.

OPPENHEIMER SON & Co., Ltd.

Handforth Laboratories, CLAPHAM ROAD, LONDON, S.W.9.

COD-LIVER OIL CREAM

Whenever there is occasion to prescribe Cod-Liver Oil this preparation will be found to fulfil all requirements as to palatability, ease of assimilation, and freedom from causing digestive disturbance.

It is specially indicated in cases of—

Delicate Children,

Bronchial conditions,

Enlarged Cervical Glands,

Persistent Coughs, etc.,

and as an ideal nutrient and strengthening agent after illness.

Supplied freshly prepared in bottles, 4/-, 7/-, and 10/-, by return, post free.

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received.

Messrs. KAYLENE, LTD.

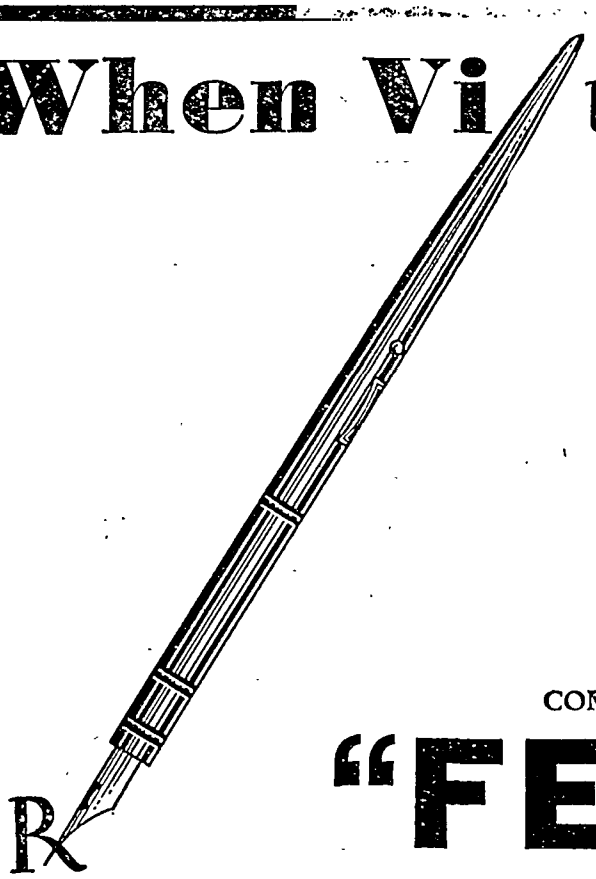
DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Physician to ———. Yours faithfully,



———, M B.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

Effective Ferrotherapy

IDOZAN IS A COLLOIDAL IRON SOLUTION, NEUTRAL, AND CONTAINING 5 PER CENT. OF PURE IRON (Fe).

One teaspoonful of IDOZAN contains 25 ctgrms. of pure iron (Fe).
One dessertspoonful of IDOZAN contains 50 ctgrms. of pure iron (Fe).
One tablespoonful of IDOZAN contains 75 ctgrms. of pure iron (Fe).

Thus, by means of relatively small doses of IDOZAN it is possible—without any inconvenience to the patient—to give much larger doses of iron than could be accomplished with many of the older preparations. In cases of severe anaemia, for instance, one may very well give the patient one tablespoonful of IDOZAN three times daily. This dosage means a daily intake of 2.25 grams of pure iron.

Packings—8-oz. & 40-oz. bottles.

ALLERGIC CONDITIONS AND PROTEIN SENSITISATION

MUCH attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner.

The substances which may sensitise are very varied (*e.g.*, animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products) and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, etc.

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured. This has been found to occur in many cases of asthma, eczema and other skin diseases.

The best of all intestinal disinfectants is Kerol, which acts as a specific cure in many of these cases.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Remarks
ON
BREECH PRESENTATION: FOETAL MORTALITY AND INJURIES *

BY
G. F GIBBERD, M B , M S , F R C S
ASSISTANT OBSTETRIC SURGEON, GUY'S HOSPITAL

Before discussing the various causes of foetal death and the types of foetal injury that may result from breech labour, we must be quite clear as to the frequency with which these catastrophies occur.

I have drawn up a table illustrating the results to the foetus of breech labour in English maternity hospitals † These figures are obtained from the latest available annual reports of the hospitals in England which publish the necessary figures It has not been possible to work out mortality rates for primiparae and for multiparae separately, since in some of these reports this information is not given.

TABLE I
FOETAL AND NEO-NATAL DEATH RATES IN BREECH DELIVERY IN ENGLISH MATERNITY HOSPITALS

	Total Number of Cases	Foetal Deaths Per cent	Neo natal Deaths Per cent
'Uncomplicated Breech	209	26	6
'Complicated' Breech	218	43	9

These figures are surely enough to dispel the old text-book inaccuracy that the foetal mortality associated with breech delivery is about 3 per cent in multiparae, and about 10 per cent in primiparae, especially when it is remembered that some of the hospitals quoted in the above table include all primiparae under the heading "complicated"

The official way of presenting breech mortality figures has the effect of hiding to a great extent the seriousness of this type of labour. We are asked to regard any breech labour in a primipara as *ipso facto* a "complicated" breech If such a classification had not received the blessing of the Obstetric Section of the Royal Society of Medicine it would probably never have been adopted. As it is, it has done more than anything else to hide the unpleasant truth about breech mortality This principle of suppressing the bad results by widening the meaning of the term "complicated" has been carried even further by some hospitals, where every case of extension of the limbs is placed in this accommodating class Since nothing can be more natural than for a woman to be a primipara when she is having her first child, none of us can seriously regard primiparity as a complication Since extension of the limbs is the rule in primiparae, and not at all uncommon in multiparae, few of us can seriously look upon this condition as a complication of breech delivery That it may be a very serious concomitant everyone will admit, but it is so much part and parcel of the presentation that it is unreasonable to dub it a complication for statistical purposes

For these reasons we have at Guy's Hospital always included primigravidae and cases of extension of the limbs in the uncomplicated group, reserving the complicated group for cases in which some additional abnormality, such as placenta praevia or prolapsed cord, is present

The following detailed analysis of 338 consecutive breech deliveries at Guy's Hospital is based on this method of classification. Breech delivery occurring in twin labour has been kept separate because, although this can reasonably be looked upon as a complication, it is a complication that seems to be beneficial, and its significance would be lost unless these cases were classified apart.

TABLE II
GROSS FOETAL AND NEO-NATAL DEATH RATES IN BREECH DELIVERY AT GUY'S HOSPITAL

	Total Number of Cases		Still births Per cent.		Neo natal Deaths Per cent	
	Primip	Multip	Primip	Multip	Primip	Multip
'Uncomplicated Breech	48	161	23	20	2	2
'Complicated' Breech	7	43	57	56	14	2
Twins	3	76	33	9	Nil	3

N B —Primiparity and extension of the limbs are not considered complications in this table

It is of course true that in the case of a macerated foetus, and in some of the complicated cases, the breech delivery may have had nothing to do with the foetal death, and it is also true that some of the neo-natal deaths may have been due to prematurity and not to any injury sustained during labour, so that in order to get an estimate of the *minimum* foetal risk associated with the labour itself we shall at least not be exaggerating if we consider only still-born, fresh foetuses in the uncomplicated group

TABLE III
PERCENTAGE OF STILL BIRTHS (FOETUS FRESH) IN BREECH DELIVERY.

	Uncomplicated Per cent	Complicated Per cent	Twin. Per cent.
Primiparae	8	57	33
Multiparae	15	40	9

This table, then, gives us a true picture of the seriousness of breech labour so far as the life and death of the foetus is concerned There is no doubt that every death in the uncomplicated group can be attributed to the essential mechanical difficulty involved in breech labour It is interesting to note that by far the best results are obtained when labour is complicated by twins The mechanical advantage of a small foetus, and of breech delivery after previous dilatation of the birth canal in cases where the breech happens to be the second foetus, more than compensate for the increased risk associated with twins generally

I have chosen these figures from Guy's Hospital to illustrate the very high mortality associated with breech delivery, because the details of all cases have been available for analysis, and from a study of these it is clear that breech labour itself—setting aside all associated complications—is responsible for a foetal mortality of not less than 28 per cent. in primiparae, and 15 per cent. in multiparae.

Apart from the associated accidents, such as prolapsed cord, the intra natal deaths are due largely to two causes.

By far the most important cause is intra-cranial haemorrhage. Since Mr Eardley Holland has described and drawn attention to the frequency of this injury, all observers have confirmed the truth and importance of his findings In his original communication on this subject in 1922 Mr Holland suggested that 75 per cent of foetal deaths were due to this cause In my own experience of post-mortem findings at Guy's Hospital I have found practically the same proportion

The second, and to my mind the only other important, cause of foetal death is asphyxia following cord compression after the birth of the buttocks This accounts for almost all the remainder of the intra natal deaths

A third cause of death is often described—namely, death from drowning due to premature inspiration I cannot help thinking that this will, in time, become recognized in its true light as a "bogey," and that the concomitant "hot towel" will become a thing of the past I do not believe that the respiratory efforts made by a foetus with

* Made in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Eastbourne, 1931

† Queen Charlotte's Hospital 1924 City of London Maternity Hospital 1928 University College Hospital, London, 1929 Guy's Hospital 1930 Jessop Hospital for Women Sheffield, 1928 Liverpool Maternity Hospital, 1929 Leeds Maternity Hospital, 1930 St Mary's Hospitals, Manchester, 1927.

its face tightly applied to the lower part of the birth canal can result in the inspiration of an important amount of liquor amnii, and even if it was able to do so, the part played by the traditional cold air in stimulating deep respiration is so negligible as compared with the effect of an accumulation of carbon dioxide in the blood, that the value of a hot towel to cover the exposed parts of the foetus must be negligible also. So far from feeling anxious when we see a partially born foetus making respiratory efforts, it would perhaps be wiser to welcome them as at least a sign of life. A hot towel in an easy breech labour is unnecessary, in a difficult case it is an impediment, and probably in no case does it prevent inspiration in a foetus sufficiently asphyxiated. Quite apart from these considerations it is doubtful if these premature inspiratory efforts are really harmful.

Apart from the danger of death, the foetus in breech cases runs an increased risk of serious injury. In the cases I have analysed serious injury occurred in 5 per cent. of living children. These injuries can best be discussed under three headings.

Injuries to Viscera

Although our accurate knowledge of intra-cranial injuries is based mainly on post-mortem findings, there is no doubt that minor degrees of intra-cranial haemorrhage and of tentorial tears are not necessarily incompatible with life. At the present time it is very difficult to form an opinion as to the late effects of these injuries. Before 1922 it was vaguely assumed that Little's disease (spastic diplegia) was due to a bilateral bruising of the brain, mainly in the region of the Rolandic areas. This assumption was based upon careful observations in cases of developed diplegia, coupled with complete ignorance of what actually happened at birth when an intra-cranial injury occurred. Since Mr. Holland has described the mechanism of these injuries it is now clear that the very last parts of the brain to be affected by the stresses and strains of labour are the Rolandic areas. An intra-cranial haemorrhage that is so extensive as to involve the upper surfaces of both cerebral hemispheres is almost certain to prove fatal. Conversely, the child with the intra-cranial injury who lives is the one in whom the anatomical lesion as we know it will not suffice to explain the signs and symptoms presented by a typical Little's disease in later life.

The difficulty in studying these cases is that apart from post-mortem evidence there is no way of being certain of the diagnosis of intra-cranial injury in the new-born. If the condition is diagnosed and the child subsequently grows up normally there is always the possibility that there never was any injury of anatomical importance. In this connexion the use of lumbar puncture in new-born infants would seem to be of little assistance, since, according to American observers who have used it extensively, quite a large proportion of infants born after normal labour have blood in the cerebro-spinal fluid. Furthermore, in the interests of the child, this procedure seems to me to be unjustifiable.

At the present time we have no accurate clinical data on which to form an opinion as to the late results of minor degrees of intra-cranial injury. I know of a child delivered by Caesarean section who has developed a typical spastic diplegia. I have seen a child born after a difficult breech labour who presented a typical picture of intra-cranial injury, subsequently grow up into an apparently normal child. Now that we have knowledge of what this injury actually is, and now that our clinical methods of diagnosing it immediately after birth are improving, we may hope in the near future to follow up such cases, and obtain some useful correlation between non-fatal intra-cranial injuries and disability in later life. At present the correlation is not obvious.

Injuries to abdominal viscera during manipulations involved in breech delivery have been very widely recognized, and although rupture of the liver and similar gross injuries may occur, their importance has probably been stressed too much. During the post-mortem examination of still-born foetuses over a period of six years at Guy's Hospital the only intra-abdominal injury met with was a case of retro-peritoneal haematoma in the region of the kidney and suprarenal. Provided reasonable care in handling the foetus is exercised, such injuries should not occur even in the most difficult breech extractions.

Injuries to the Upper Limb

These are by far the commonest injury in difficult breech cases, and are nearly always the result of manipulations to extended arms. The injury may pass unnoticed for several days, and as early diagnosis is very important, a careful examination should always be made as a routine in all breech infants. When it is discovered that the infant has limitation in the movements of its arm the cause is nearly always either an Erb's paralysis or a fracture of the upper end of the shaft of the humerus. A physical examination will reveal which of these causes is to blame. An Erb's paralysis should be treated by putting up the arm in the "Israelite position," and allowing active movements daily when the splint is removed for bathing purposes. If this treatment is started at once the prognosis is very good indeed.

A fracture of the shaft of the humerus is best treated with a small straight Thomas arm splint, using a thin elastic band as extension. Although less elaborate methods of splinting will suffice, this method has the advantage that it allows for dressing and undressing the infant without disturbing the fragments. Union is firm within a week to ten days, after which the splint may be discarded. It may take months for the excess of callus which usually forms to be absorbed, but the ultimate results are excellent.

A fractured clavicle is often not noticed until attention is called to it by a mass of callus at the site of fracture. It calls for no special treatment beyond careful handling of the infant until union has occurred.

Injuries to the Lower Limb

These are very much less common, fracture through the upper part of the shaft of the femur occurring only very rarely as the result of unjustifiable force being used for groin traction with extended legs. The upper fragment is flexed, externally rotated, and abducted, and as it is impossible to alter its position by any method of splinting, the best method of treatment is to bring the lower fragment into line with it. This can be done best by merely bandaging the thigh to the trunk so that the thigh is flexed, abducted, and externally rotated. A miniature "gallows" extension or any other forms of leg splint fail completely to get the two fragments into line, and although they may simplify the nursing of the infant, they should never be used. Firm union occurs within ten days, and after the excess of callus has been absorbed the ultimate results are excellent, both anatomically and functionally.

Summary

In view of the fact that the foetal mortality rate in breech labour is usually under-estimated it seems a pity that a classification which tends to hide the dangers has been so widely adopted. It would seem better to regard a "complicated" breech as one in which some additional obstetric abnormality is present, and under the term "uncomplicated" to include primipara, and cases where extension of the arms occurs.

On this basis of classification the gross mortality rate for uncomplicated cases is about 30 per cent. for primiparae and about 20 per cent. for multiparae, and after making all possible allowances foetal death rates of 28 per cent. and 15 per cent. respectively can be taken as the minimum estimate of the dangers associated with the breech labour itself.

Of non-fatal accidents to the foetus, injuries to the limbs occur in about 5 per cent. of cases. Early diagnosis of the injury is all-important, since early treatment is usually rewarded by excellent recovery.

The late results of non-fatal intra-cranial injuries are at present uncertain, and sufficient reliable observations are not yet to hand to justify us in forming definite views.

ANTE-NATAL TREATMENT OF BREECH PRESENTATIONS *

BY

GERTRUDE DEARNLEY, M.D., B.S.LOND.

Breech presentations are found very frequently in the ante-natal period up to the 34th week. After this time they are much less common, as spontaneous version to a vertex presentation occurs in a large proportion of cases at about the 34th to the 35th week of gestation. In 100,000 cases of labour Pinard observed 3,301 breech presentations —about 3.30 per cent. These statistics include premature as well as full-time labours. If full-time labours are considered only we find 1 in 62 cases. The foetal mortality in breech cases is nearly 10 per cent. ; the figures given at Queen Charlotte's Hospital being 11 per cent. in primigravidae and 8 per cent. in multigravidae.

There are two main reasons for preventing breech labour as often as possible, and these are (1) the higher foetal mortality in breech labour; (2) the disadvantages to the mother: (a) the greater risk of exhaustion following a long labour, and (b) the greater liability for lacerations and damage to the pelvic floor, and therefore a greater risk of sepsis.

In every case of labour it is important to secure for the patient as easy a labour as can reasonably be achieved for her. The length of time required for convalescence after a long and trying confinement is much greater than is necessary after a relatively normal labour. This is particularly true of the return to normal as regards the patient's nervous system. It is also quite unjustifiable to run any risk of having a still-born child. For these reasons it is now the common practice to do external version in the ante-natal period for all primigravidae, except under exceptional circumstances. It is my custom to do version also for multigravidae, partly to diminish the foetal risk, and because I have learnt from patients who have experienced labour, both with a vertex and a breech presentation, that in the majority of cases the suffering in a breech is far greater than in a vertex. There is also another reason for performing version in the ante-natal period, and this is of importance. In any case the most reliable guide for ascertaining the relative size of the head and pelvis is by pushing the child's head into the pelvis. For this test it is essential that the presentation should be a vertex.

As spontaneous version so often occurs, it is unnecessary to interfere in any way until after the 34th week. The ideal time for doing version in a primigravida is about the 35th week. At this time, as a rule, the presenting part has not descended into the pelvis. It is often possible to do version easily without anaesthesia, and this is a great advantage, as it prevents the obstetrician from using undue force. If the patient is very nervous or the abdominal muscles are very strong an anaesthestic may be necessary. A thorough dusting of the abdomen with talc powder is helpful, and the manœuvres should be done gently and with firmness. In some cases in which the presenting part has already engaged it is very helpful to raise the foot of the couch on two chairs for a few minutes before starting version. In other cases the presenting part can be pushed out of the pelvis *per vaginam* before starting. Where an anaesthetic is needed it is wise to delay version until the 37th week, in case manipulations should start labour.

I have never seen any serious complications follow version. In one case only there was a slight ante-partum haemorrhage. This cleared up quickly and the patient went to term and had a normal delivery. It was a case of breech with extended legs in a primigravida. An anaesthetic was given and a good deal of force was used to turn the child. Cases of fairly severe ante-partum haemorrhage after version under anaesthesia have been reported.

METHOD OF PERFORMING VERSION

The first essential is that, before an attempt to turn the child is made, the presenting part shall be fully pushed out of the pelvis; most failures to turn are due to the neglect of this preliminary movement. The head of the child is then seized with one hand and the breech with the other hand. The head is next pulled down towards the pelvis and the breech pushed up away from the pelvis. The direction of choice is to pull the head down towards the pelvis away from the back of the child. By this means the flexion of the child will not be disturbed. If version fails in this direction, the other direction may be tried and often succeeds without harm.

Immediately after version the head will often sink low into the pelvis; but if this does not occur an abdominal binder is applied and the patient is examined again in a week's time. The use of a binder is particularly to be recommended after version in a multigravida, where the abdominal wall is often weak, and the mal-presentation therefore liable to recur.

In a multigravida version is usually done at a later date than in a primigravida, but there is no harm in doing it at the same period of gestation. Some women complain of discomfort from the hard head in the fundus, and by doing version the patient is made much more comfortable. It is not uncommon for women to bear increasingly large children. This seems to be specially true of women whose first child was small. For this reason it is unsafe to assume that because a woman has had one child normally that all subsequent pregnancies will be normal, as is frequently done. In my opinion this is an additional reason for turning a breech presentation in a multigravida, so as to be in the position of being able to test the relative size of the head and the pelvis.

Where version has failed it is usual to wait for a few days, when the patient is seen again. In a number of cases of this kind it will be found that spontaneous version has occurred in the interval. The attempted version seems to start spontaneous version, particularly if the presenting part has been pushed out of the pelvis.

After failure to do version in a primigravida it is very instructive to have an *x*-ray photograph taken so as to see exactly the position of the child. It is very easy to miss a breech with extended legs by abdominal palpation alone. In order to avoid this mistake the following points are of use:

The presenting part is relatively small and more conical than one would expect.

The head in the fundus is often difficult to distinguish and its mobility is impaired, but small parts can usually be felt near it.

* Read in opening a discussion in the Section of Obstetrics and Gynæcology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

The whole uterus is narrower from side to side than usual. On vaginal examination the presenting part is small and soft.

It is not uncommon to mistake a deeply engaged breech with extended legs for a vertex, and if any doubt is felt it is best to have an *x*-ray done.

In an occasional case of breech with extended legs spontaneous version occurs. This happened in a case at Queen Charlotte's recently, in which the *x* rays showed a breech with extended legs. The patient was delivered of a vertex normally. It is a very rare occurrence.

Occasionally an unsuspected twin pregnancy is found by *x*-ray examination in cases where version has failed. In cases of breech presentation where hydramnios is present it is very unusual to be able to maintain a vertex presentation. In mild cases version is easy, but the presentation is apt to recur.

Version in Breech with Extended Legs.

It is revealed by *x*-ray examination whether the legs are fully extended—that is, whether the child's feet are lying close to the head or not. If the legs are extended but not close to the head, and therefore where there is often fairly good flexion of the child's body, it is possible to turn the child with anaesthesia without risk.

If the legs are extended fully and there is also extension of the child's body it is wiser not to do version, as where this is performed with force under anaesthesia damage may be done, and also there is a risk of bringing a hand or arm down by the side of the head, which will cause difficulty in labour. In such cases it is best not to attempt version.

THE MANAGEMENT OF BREECH LABOUR*

BY

ALECK BOURNE, M.B., F.R.C.S.

OBSTETRIC SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL; SENIOR OBSTETRIC SURGEON, QUEEN CHARLOTTE'S HOSPITAL

The risks of breech delivery to the child and, to a lesser extent, to the mother, are great enough to call for considerable skill in its management, and, in view of certain new observations which have recently been made, it may be of interest to devote a little time to its consideration. Expressed in figures, the results at Queen Charlotte's Hospital show a foetal mortality of 11 per cent. for primiparae and 8 per cent. for multipara. These percentages may be a little higher than those of some private practices, because a large number of breech deliveries at the hospital are sent there as emergencies in obstructed labour due to extended legs.

Before describing any details of management let us first consider the particular dangers to which the child is exposed. An appreciation of the nature of the risks will assist in understanding the reasons for the rules of management.

Causes of Foetal Death

The causes of foetal death as shown by post-mortem examinations are intracranial injuries, injuries of the abdominal viscera, and asphyxia. Up to recent years it was thought that the predominant danger was asphyxia, but an investigation by the President, Mr. Eardley Holland, and his fellow workers, has shown that the majority (14 out of 16 cases examined) of stillbirths are due to tears of the intracranial septa leading to intracranial haemorrhage. It is not necessary to go into the exact nature of these injuries to-day, but the mere fact of their occurrence shows that sudden severe compression of the head is the most formidable risk which the foetus has to face. Herbert Spencer showed in 1891 that abdominal injuries of suprarenal capsules, kidneys, liver, spleen, and other organs, as well as intracranial lesions, all involving haemorrhage, were to be found in nearly all still-born children, and that a high proportion of abdominal injuries occurred in breech-delivered babies. He showed that intracranial haemorrhage occurred oftener in still-born breech babies than in spontaneously delivered vertex cases. Spencer considered that these injuries were caused by too great pressure on the baby's body, as often follows premature rupture of the membranes, too rapid delivery, and also improper handling of the child's trunk as it is in the act of being delivered. Some of these risks are unnecessarily incurred in an attempt to deliver quickly to save the child from asphyxia, the result of age-long teaching that this is the greatest danger. On the other hand, too great deliberation in extracting the head will certainly cause asphyxia. In the management of breech labour we are therefore sailing between two rocks, and it is incumbent upon us to steer so carefully as to avoid collision with either.

Considering the lesser danger first—asphyxia—we have little control over the death of the child during the first stage of labour by prolonged pressure after a rupture of the membranes. Whether it is due to true asphyxia, caused by pressure of the uterus on the cord and placenta against the child's body, or by depression of the medullary centres, we are often powerless to expedite the dilatation of the os without risk of serious injury to the mother. The child is more likely to suffer from the almost constant pressure of an irritable uterus than from the effects of strong but separate rhythmic contractions with good relaxation between the pains. If, therefore, the uterus does not relax sufficiently, and the foetal heart is quickening or failing during the first stage, it is well to give the mother morphine and hyoscine hypodermically, and chloral by the mouth. A slow dilatation, especially after half completed, can often be expedited by pulling one foot down into the vagina. When the os is fully, or nearly fully, dilated, it is well to examine vaginally to find out whether the feet are within reach through the os, or out of reach—that is, displaced upwards by extended legs. I advise that this should be done in order that if the legs are extended they should be brought down at the beginning of the second stage of labour, except the child be so small that no obstruction need be anticipated. Much discussion has taken place on the question of whether extended legs should be brought down unless, or until, actual delay due to obstruction has occurred. My own views on this point are quite definite, and are founded on painful experience gained during the early days while a resident medical officer. I believe that it is wise to bring down at least one leg, and often two, depending on the size of the baby, in all cases as early as the os will conveniently and safely admit the hand.

Difficulty due to Extended Legs

Before we go further, I would like to spend a moment in explaining how I think extended legs cause difficulty in labour. The text-books state that the delay is due to the inability of the child's spine to flex laterally and follow the curve of Carus of the birth canal, by reason of the splinting of the legs as they lie alongside the child's abdomen and chest. I could imagine that the spine might be splinted if the two rigid bars were bound to the spine after the manner of actual splints, but it is absurd to suppose that the spine can be prevented from making a relatively small curvature laterally by two non-rigid limbs which are not in any place bound to the dorso-lumbar spine. Mere apposition of the legs to the child's abdomen

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

cannot have any possible effect in preventing the spine flexing in any direction. The first attempt to bring down the leg in a case of impacted breech delivery makes quite clear the reason for delay or obstruction. As the hand is passed up alongside the child's impacted trunk it is readily conscious of the tightness of the fit, and how fully the available pelvic capacity is filled by the body of the child. If a cross section through the abdomen and thighs, with the legs in the extended position, be examined, it can easily be realized what a great deal of extra pelvic accommodation is required to pass the child without difficulty. The mechanics of the difficulty are merely one of relative sizes of the cross sections of the body and the pelvic cavity. When the child is quite small there is plenty of room, and obstruction does not arise, though, surely, if the legs acted as splints even the premature spine would also be unable to flex laterally. Lastly, in most cases the difficulty is relieved by bringing down one leg—that is, by reducing the cross section of the foetus. But if one leg is left extended, it should, according to the orthodox theory, be sufficient to act as a splint and prevent spinal flexion.

I believe, therefore, that the indication for bringing down the leg is present in all cases where the child is of average or large size. I admit that here and there we see the seven- or eight-pound baby expelled with the legs in the extended position, and if they had been brought down in such a case the operation would have been done unnecessarily, but, as I said at the outset, it is a far more serious blunder to fail to bring down legs before impaction. The result is the inevitable difficulty of a struggle to reach and flex the legs with all the risk of vaginal and bladder injuries and foetal fractures. All who have had this experience in a really difficult case will, I feel sure, agree with me that it is a lesser mistake to bring the legs down easily at an early stage, before deep descent into the pelvic cavity, in an occasional case where it might not have been absolutely necessary. Hence, my rule is to examine for the feet when the os is nearly fully dilated, and, if not felt, to pass the hand up and bring one, or both, down after making an estimate of the probable size of the baby. Having brought the legs down they should be folded, as far as possible, in the normal position by the buttocks. The reason for this is twofold. First, it may be possible to attain a little wider dilatation of the os as the uterus pushes both buttocks and legs through; and, secondly, that the sight of a foot at the vulva provides such a strong stimulus to pull on it in order to hurry the labour that it is better to avoid the means of the temptation. It is of the greatest importance not to pull on the child, especially if the mother is a primipara, at this stage. I believe that more babies are lost in breech labour indirectly by this cause than by any other in the management.

Extended Arms

When, therefore, the legs are in normal position, with the feet alongside the buttocks, the accoucheur should wait with the utmost patience. The only assistance that may be given for ordinary mild delay is pressure on the fundus with each pain. As the feet appear at the perineum they should be disengaged, but still there should be no pulling on the child, and as the body appears it should be wrapped in a towel, and grasped by the ankles only. At this point it is, as stated above, most important not to hold the child's body. It is by this rather excited grip of the abdomen around the loins that the suprarenals and other viscera are liable to be injured. A grip of the ankles is easy and firm. At this stage an anxious moment arrives. While the body is carried forward away from the perineum by the right hand gripping the ankles, a finger of the left hand is passed along the child's chest to find the elbows. If they are not felt folded on the chest, the arms are extended, and a most difficult manœuvre is necessary to bring them down. Extended arms are, in my opinion, the most serious of the common complications of breech labour. It is not only usually difficult to pass sufficient of the hand past the child's body to reach the arm high enough to flex it, but it all has to be done fairly quickly. When extended legs are being flexed, the operation can be done with the greatest deliberation without harm, but if too much time is taken up in flexing the arms the child may be lost by asphyxia.

It is necessary to remember that everything possible should be done to avoid extended arms. The cases fall into two groups. The first group is primary—that is, the arms are extended when legs are extended as a foetal attitude before labour begins. This was once shown by the late Dr. Briggs of Liverpool, by a very early *x*-ray photograph during pregnancy, before the sixth month, while, since this publication, we have very often seen extended arms in *x*-ray photographs taken at the end of pregnancy. Of this primary group it is obvious that we have no control. The secondary extension is produced during labour entirely by pulling on the foetus during delivery before the elbows can be reached and hooked out from the perineum. If the exciting cause be pulling on the child's body, the predisposing cause is insufficient dilatation of the cervix as the comparatively narrow breech passes through it tightly stretched. We can imagine, as the child's body, with the arms properly folded on the chest, scrapes past the thin, tight edge of the os, the elbows will be caught and lifted up above the shoulders. Not only is the incompletely dilated os responsible for this displacement of the arms, but also the too close pressure on the child's trunk by the incompletely stretched vagina which is liable to occur in all primigravida. We can see, therefore, now the useful effect of allowing both breech and legs, in a flexed position, to pass through the os and vagina in one mass, for they form a larger mass than the breech alone with both legs either extended or brought down, and, therefore, the os will be dilated to a greater extent, with consequently a smaller risk of the arms being displaced upwards.

Recovery of the extended arms is clearly described and illustrated in all the text-books, and need not be given here. There is a useful tip, however, which I learnt by seeing Potter deliver a breech presentation. Taking care not to pull too hard on the body so as to imprison the arms firmly between the head and the brim, press the axillary border of the scapula firmly inwards. This will have the effect of bringing the humerus downwards within reach of the internal hand. Observation of the baby's arm and scapula will show that the humerus can only be fully extended above the head by a movement of the scapula outwards, and it can easily be demonstrated that pressure of the scapula in the opposite direction will have a corresponding effect on the movement of the humerus.

Delivery of the Head

On the delivery of the head largely depends the fate of the child. If done too quickly from a primigravida, especially if the head is not well flexed, there will be too sudden moulding of the cranial bones, with the serious risk of tears of the dural septa and intracranial haemorrhage, while if too much time is allowed, the child will die of asphyxia. Of these dangers the commonest is to deliver the head too quickly. As a stimulus to excited action we have, first, our teaching, and instinctive knowledge of the possibility of asphyxia, and, secondly, the alarm occasioned by the frequent sight of the child's chest attempting premature inspirations. We have been taught

that by these movements the child is sucking in quantities of liquor amnii by which it will be drowned. Surely the child's mouth and nose are pressed tightly against the wall of the vagina, and not free in a bath of fluid, so that literally no liquor amnii can be inspired at this stage of delivery. It is a fallacy that the child can drown himself during extraction of the head, and therefore the inspiratory movements should not influence the accoucheur during his efforts to deliver the head.

The first point to try to be sure of is whether or not the child's head is flexed as it lies in the antero-posterior direction—that is, with its back facing anteriorly. Difficulties will depend more upon absence of flexion than size of head and pelvis; in fact, where the pelvis is normal incomplete flexion is the cause of nearly all difficulty. When, therefore, can we *suspect* that flexion will be imperfect? First, in all cases in which legs and arms have been extended, then in most cases in which the child's body has been pulled down by the contracting uterus, and, rarely, in some cases of flat pelvis. We can, however, *expect* complete flexion in all multigravida where legs and arms have been normally flexed, in all small or premature babies, and in nearly all cases in which the delivery of the child's body has been accompanied by firm pressure on the head through the fundus of the uterus. The last contingency implies the necessity in all cases of instructing the nurse to press firmly on the fundus during the delivery of the body.

Three Clinical Types

In practice, therefore, we have three clinical types. The first is where a multipara has delivered herself of the legs, body, and arms normally and easily. Here we may assume the head will be flexed and give no trouble. The direction is to deliver by the simplest method, which is to grasp the feet in the right hand and lift them gently and gradually up to the mother's abdomen, while the left hand, or a nurse, presses firmly above the symphysis. No other manipulation, or grasp, of the child's body is necessary.

The second clinical type is the primigravida who has been slow and "difficult," possibly with some slight general contraction of the pelvis. Here the head *may* not be fully flexed, and, therefore, for these patients it is well first to pass a finger up to the chin and feel whether it is pressed well down on the sternum. If it is flexed, deliver the child by a grip which will allow some harmless traction —that is, by the so-called Prague manœuvre. Take the feet in the right hand and place the first and second fingers over the child's shoulders. Traction is made on the shoulders, while the feet are carried to the mother's abdomen as the head is pulled down, while, again, the nurse presses firmly above the symphysis. Care must be taken to deliver the chin and face slowly from under the perineum; in fact, as soon as the mouth and nose are liberated there should be a pause for the sake of both the head and the perineum.

The third clinical type is that in which we can assume that the head is extended; for example, where we have already brought down arms and legs from the extended position. It is also likely to be extended if it does not descend well through the brim, and thus appears to be high up with stretching of the neck. Here the "jaw traction" method should be adopted. The right hand is passed into the pelvic cavity so that the index finger slips readily over the lower jaw into the mouth, the child's body lying astride on the right forearm. The first and second fingers of the left hand are placed over the shoulders. Before there is any traction made on the shoulders the head should be flexed by gentle traction on the lower jaw and simultaneous firm pressure on the fundus. Usually the head can be made to flex by this manœuvre, and then firm traction is made on the shoulders, which are, as the head descends, carried towards the mother's abdomen.

Some accoucheurs prefer to deliver all difficult cases by forceps, but of this I, personally, cannot speak from experience.

THE PROGRESS OF ANAESTHESIA*

BY

R. J. CLAUSEN, M.C., M.B., B.S.

It is no doubt fairly generally believed that very considerable progress has been made in recent years in the art or science of anaesthesia, and that great benefit has resulted therefrom to those undergoing surgical operations. New drugs, machines, and methods have been introduced from time to time with a greater or less flourish of trumpets the echoes of which have occasionally reached the public through the daily press. It has in fact occurred to me on more than one occasion that a patient has remarked in the course of preliminary conversation how much these things have improved since the occasion of a previous operation, perhaps ten or twenty years ago, and what wonderful people we doctors are.

Such a state of mind is doubtless very beneficial to the patient, but the flattery though pleasing to us seems hardly justified if, as may well be the case, nothing more remarkable is about to be given than ether or chloroform on a mask, perhaps preceded by a hypodermic injection of 1/100 grain of atropine. However, there is no doubt that the resources at our command have considerably increased, and the object of this paper is to suggest that full advantage has not been taken of them, to inquire into the causes of this neglect, and, if possible, to suggest remedies for it.

It will be obvious that without a very exhaustive inquiry it is impossible to assess the state or progress of anaesthesia as a whole throughout the land with any degree of accuracy, and an incomplete inquiry may be as misleading as none at all or even more so. For operative surgery is carried out not only in the accessible city hospitals but also in numberless small hospitals, nursing homes, and private houses scattered over the country. An example of an incomplete inquiry was provided in a recent number of a periodical devoted to anaesthesia and analgesia, in which a writer made a rather ambitious attempt to survey world conditions. Such an article must be either very general or quite complete, but the author made the mistake of mentioning a few names of individuals; I was mentioned, for instance, as having the only large experience of ethylene in this country, but I am sure that the President of this Section, to name only one other, has a very much greater experience of this anaesthetic than I can claim.

For the purposes of this paper, therefore, I have not attempted any inquiry whatever, and it follows that any criticisms I shall make may be entirely unjustified. A good deal of information may, however, be gathered and inferences drawn from articles and correspondence in the journals, conversation with colleagues, the equipment of cottage hospitals and nursing homes, and so on. Further, to establish my credentials at any rate as regards London, and to avoid any suggestion of individual prejudice, I may mention that during the last ten years I have held resident or honorary anaesthetic appointments in nine hospitals, of which two have medical schools attached. It should also be understood that conditions in this country also

* Read in opening a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

e under consideration, and that no attempt is made deal with anaesthesia abroad. It is probable that the ost outstanding differences in the practice of other untries arise from the fact that in them the majority operative work is carried out in large hospitals or nics, and very little in private houses or nursing homes. In the large teaching hospitals here, which are of urse the most easily accessible for inquiring visitors, the ndard is probably fairly high, but the adoption of ricate or experimental methods may be hampered by e necessity for teaching general principles and routine ethods to students, who cannot be made fully conrsant with all new developments. On the other hand, ere is at times an unfortunate tendency for some new ethod or technique to be exclusively used in the spital of its origin, with the result that students acquire exaggerated belief in the benefits of this method d a lamentable lack of knowledge of others. As in her branches of practice, of course, the newly qualified an is only beginning to learn, and he may have to rget a good deal of what he saw and learnt as a student; it in the brief time that he then has he should be enabled acquire a general foundation on which to develop a ore specialized knowledge later, should the occasion arise. Before proceeding to a more detailed criticism of our esent methods it would be as well to point out that though the subject may appear to be of most interest this Section, yet actually it concerns the surgeons more osely. For as Dr. Torrance Thomson recently pointed it in the *British Journal of Anaesthesia*, the surgeon must alize the importance of our work if progress is to be ade, since without his interest and co-operation we can ake but little advance, notably in the field of gas-ygen anaesthesia, or any local methods.

SOME CRITICISMS AND SUGGESTIONS

Dealing, then, with our present methods, the following iticisms and suggestions are put forward, though naturly in the space of such a paper as this it is not possible go into very great detail.

I

Insufficient individual attention is given to patients, rticularly in hospital, but also in private practice, since erating theatre habits and customs are acquired in ospital by physicians, surgeons, and nurses.

The saying may be familiar that "routine anaesthesia bad anaesthesia," and this may be correct, but nevertheless a good deal of routine is useful and necessary in our ork, to enable it to be smoothly and easily done. Probbly most anaesthetists adopt and perfect some standard chnique, which tends to be applied to every patient, erhaps without great regard to their needs or desires. It probably true that for operations of reasonable length—ay, under an hour's duration—on healthy persons and here little shock is expected, the choice of anaesthetic akes little or no difference to the recovery of the patient nd but little to the immediate discomfort of the operaion. However, a large proportion of our cases do not ome into this favourable category, and if the scope and dvantages of new methods are not realized these less ortunate patients may suffer.

Besides the lack of adaptation of anaesthetic methods o individual cases there is often a striking lack of regard or the patient as an individual. Both failings are due to r encouraged by the system in large hospitals, where the naesthetist is confronted with a long list of major operaions of all descriptions, on patients he has never seen efore and knows nothing of, while conditions are not mproved by a general atmosphere of hurry and an im-atient surgeon striding from room to room exclaiming "*Let's get on with it.*" Probably arising from these conditions there is sometimes a tendency to regard an anaesthetic as a standardized article which can be applied indiscriminately to any patient, and an anaesthetist may be asked to give his services, no other information being given him about the patient than the nature of the operation it is proposed to perform.

It is interesting to see to what extent the individual patient may be lost sight of in hospital; in the course of instructing students I have often asked, "Who is the most important person in the theatre?" but needless to say I have seldom had the correct reply. A friend with whom I was discussing this subject made the illuminating remark that little else was to be expected so long as the architects designed hospitals with a magnificent front door for the lay committee, staff, and students, whilst patients entered by an underground passage at the back. I do not suggest that a radical reform of hospital architecture will greatly benefit our work, but I cannot help feeling that there are many perhaps apparently trivial points in the treatment of patients which could be greatly improved.

For example, it is, I suppose, laid down somewhere in the regulations that the head must be low when anaesthesia is induced, and consequently a nurse will often take away a patient's pillow and leave him nearly flat on a trolley or table in a position of great discomfort at a time when every effort should be directed towards making him as easy and comfortable as possible. Or, in a hospital which I visit, though a sorbo mattress had been provided for the table it was very difficult to get it used, the reason being that it made the movement of the patient into the lithotomy position a little more awkward, so instead a thin folded blanket was used on the metal-topped table.

Just as every surgeon should undergo an operation or two, and every anaesthetist a few anaesthetics, for instructional purposes, so it would be of value in the training of theatre nurses and sisters if they were dressed, towelled, etc., as for operation and placed in the appropriate position on the table for an hour or so. The incidence of post-operative headache, backache, and even of chest complications might be thereby materially lessened. Another striking example of the way in which the individual can be overlooked, with results that can only be detrimental, is shown by enthusiastic residents and others, who often indulge in vivid discussions in the presence of the next patient while perhaps still wearing bloodstained garments; I have seen a house surgeon actually brandish a fresh prostate gland dripping with blood over the trolley on which a conscious patient was waiting, while he discussed its points with the surgeon.

While the patient may thus be lost sight of, a tendency sometimes appears for the theatre to become a stage on which the star performer displays his skill, supported by leading lady, minor characters and chorus; for some obscure reason it often seems to be expected that the anaesthetist should supply the comic relief, while in addition he is expected to be a sort of stage hand and property man, manipulating the lights, table, suction pump and so on.

In only one textbook on anaesthesia so far as I know is there a chapter dealing with the subject from the patient's view-point, and that book is not an English one. The matter, however, seems one of importance and deserving of attention in the teaching of anaesthesia.

II

The use of mask and drop-bottle methods with chloroform and ether is still too prevalent; the ritual act of dropping liquid on a mask is however firmly established, and alternatives may still be regarded with suspicion.

The mask and drop-bottle have advantages, of course—for example, simplicity, portability, ease of control and so on. Their use, however, should be restricted if possible to induction, and if chloroform or ether anaesthesia is to be maintained for long periods it should be with vapour methods and some amount of re-breathing, preferably with oxygen, the value of which cannot be too highly stressed.

It is not uncommon for protests to be made against the growing complication of anaesthetic procedures, and for the claim to be advanced that the simplest methods are necessarily the best. This may be so in some cases, but actually the best method is that which ultimately gives the best results to the patient. Naturally, if a man arrives with an elaborate machine which takes a long time to erect, wastes everyone's time, and then gives a bad anaesthetic, he deserves some censure; for, besides his other faults, he may have brought a good method into disrepute. On the other hand, if he only spends his own time and his results are good, no surgeon has a right to quarrel with his methods, for we do not attempt to dictate what tools the operator shall use. There are those who support the plea for simplicity by using but few and simple instruments, but even these possibly forget the enormous complication of preparation, sterilization, etc., which precedes the actual entry of the patient.

Open ether, once claimed as the safest and best anaesthetic, has been described as a method invented by amateurs for amateurs; it still has many supporters, though it is probable that as most successfully practised it is far from "open." I can remember the time when the method was introduced into my hospital, which may have been a little backward in this respect, as the latest novelty from America. Its success was rapid and its vogue widespread, and closed methods which had been used with but few exceptions since the introduction of ether were largely abandoned for some years; for the open method first showed how ether could give complete relaxation with relative safety and without limitation of oxygen.

As a result of the work of Haldane, Henderson, and others, the value of re-breathing and the dangers of prolonged open etherization first came to be recognized in America, where a return to closed methods with re-breathing was initiated which later spread to this country. Open ether, however, will die hard, for apart from its actual advantages there is a frank and reassuring sound about its name which cannot fail to be attractive.

III

Local, regional, and spinal methods are not exploited as fully as they might be.

It is commonly said that local anaesthesia is widely used on the Continent because there are no good anaesthetists there, but the converse may well be true, that general narcosis is often unnecessarily used here because few people trouble to master the technique of other methods. It is also said that the people of this country are by their temperament unsuited to local methods, but this is probably in the main not true; at any rate, the behaviour of patients under spinal is usually good and helpful, though naturally the whole theatre method and organization must be altered when dealing with conscious patients.

It is a striking fact how many persons, particularly women, will say, "Oh, doctor, I don't mind the idea of the operation, but I do dread the anaesthetic." Of course, many of these might change their minds when actually confronted with an operation in the conscious state, but the benefits conferred by intelligent pre-medication must not be forgotten in these circumstances.

I have heard the methods of anaesthesia in a Continental clinic summarily dismissed as "a combination of local and straps," but I have often thought that an intelligent use of suitable straps would serve to [illegible] the patient in some of the fantastic operating [illegible] very much better than the makeshift of pillows sandbags which we use, and would thereby facilitate the work of the anaesthetist.

Spinal analgesia is being fully dealt with in another paper, so I will not enter into any detail. It is a [illegible] which is constantly cropping up, for the method is [illegible] covered, written up and more or less widely adopted [illegible] few years, being presumably forgotten in the interval. [illegible] present, needless to say, is a "boom" period. Whether advocating its wholesale use throughout the body, as some, or its routine use for abdominal work, I believe it to be a very valuable aid in many difficult cases, and one to be maintained in an effective state, so as to be available when required.

IV

The advantages of gas anaesthesia, and notably ethylene, are not adequately utilized.

Nitrous oxide and oxygen anaesthesia received an artificial impetus in the later stages of the war, having proved successful in the repeated anaesthesias on shocked and debilitated patients then met with. Later, however, the method was largely discredited in this country owing to its indiscriminate application to unsuitable cases, with inadequate preparation and inefficient apparatus, while its necessary limitations were not realized by operators. I fully agree with the authors of a recent textbook on anaesthesia, who say that "the apparatus available in England has tended to hinder the effective adoption of the method in this country."

It is unfortunate that the recent revival of gas-oxygen here has been attended by, if not actually due to, the use of imported machines, but there can be no doubt that these show considerable advantages, except perhaps in price. A similar lack of enterprise is shown by our engineering firms with regard to electrical suction and pressure pumps for surgical and anaesthetic use, for most of those sold by the instrument dealers are of foreign make.

As regards gas apparatus, there are those who claim that they can give a good anaesthetic with no more than a cylinder of each gas, connected to a bag and mask, or who criticize certain machines on the ground of their complication of dials, gauges, etc., which distract attention from the one essential—namely, the patient. However elaborate the machinery used the condition of the patient must remain the ultimate indicator and control, but the more refined the apparatus used—that is, the more accurately it is capable of giving and maintaining any desired mixture—the better will it serve both novice and expert. In this connexion, I have not yet heard an anaesthetist, or a surgeon, protest at the complication of his motor car, or complain that the number of dials and "gadgets" on the dashboard interfere with his attention to driving.

Wherever possible, in both major and minor surgery, gas-oxygen should be preferred to ether alone, though in many cases small amounts of the latter may be used in addition, while, where circumstances do not prevent it, ethylene should often replace nitrous oxide. In midwifery particularly, gas-oxygen is undoubtedly the ideal anaesthetic, and should be much more widely used. There are of course gas enthusiasts who will not tolerate even the smallest amount of ether, just as there are local enthusiasts who have no objection to injecting unlimited drugs but will not hear of giving any by inhalation. Personally I see no reason why the fullest use should not be made of combined methods, which have many advantages.

Ethylene is usually condemned on the ground of explosive risk, but in view of the many risks we let pass unnoticed this shows a curious lack of proportion. For example, the

now an enormous death rate from the entirely preventable sease of "motoring," but I believe I am right in saying iat neither this Association nor the profession as a whole is taken any steps to deal with it Actually I believe the robability of explosion with ethylene is little if any eater than with gas oxygen ether, or oxygen ether, and t present fires, explosions and fatalities are by no means nknown in our theatres, but in certain circumstances the sulting explosion with ethylene would certainly be more vere and deadly

The widest field for gas anaesthesia has been in the past s use for dental extractions in the chair, and though this now smaller owing to the increase of local and regional ethods, yet there are many cases in which it will be pre rred In patients able to co operate and in the absence f nasal obstruction or gross deformity it should always e given by the nasal route and the mouth properly acked off before extraction is begun The advantages of his method—namely, comfort for the patient, speed of nduction, safety, absence of cyanosis, and prolongation f anaesthesia if required—are so manifest that it is surpris ng that other methods are still tolerated and that full face nask induction is still taught as the routine

For long oral operations, as for other head operations, ome form of intubation is required, preferably using gas xygen, at any rate for maintenance, but it is to be hoped hat the vogue for the endotracheal insufflation of gas ixtures in all cases has now passed, and that this is no onger regarded as providing a short cut to good anaesthesia Gas oxygen, however, depends for its success on free breathing and exclusion of air, and though in general sur gery these may as a rule be obtained with the ordinary nask, yet there may be some occasions when intubation of he larynx may be desirable to ensure these conditions

V

The advantages, or rather the necessity, of adequate pre medication are not fully realized

It often seems to be thought that all that is possible in this respect has been done when 1/100 grain of atropine has been given, and this routine is often hard to break away from There are, I believe two reasons for giving atropine before anaesthesia the first theoretical, because it prevents vagus inhibition of the heart, the second prac tical, because it dries up the mucous and salivary secretions of the mouth respiratory tract I am not in a position to discuss the former, and suspect that the latter is the only one of benefit The same result, drying of the mouth, is obtained when morphia alone is given, though possibly not to the same extent, and it is probable that atropine could often be omitted with advantage, it has no sedative effect but on the contrary a stimulant one, and may facilitate the onset of shock instead of delaying it as does morphia

Morphia or its equivalent is essential if good results are to be obtained from gas oxygen, and to get a good effect it may be given in a divided dose Further, in long opera tions an additional injection may be necessary, while where it is known that it will be needed after operation it is often useful to give it before the end in order that it may have taken effect before the gas anaesthesia is over

In a hospital where both are given there is a striking contrast between the placid and quiet morphia patients and those who have had atropine only, the latter being bright eyed and apprehensive I believe that no patient should come to general or local anaesthesia for any serious operation without preliminary sedatives of the morphia type or an adequate dose of one of the "basal anaesthetics" unless there are real contraindications of which however, there can be but few There is however, a strong pre judice against preliminary morphia, dating probably from the days when induction with open chloroform was the rule In this case it is undesirable, for the combined effect so depresses respiration that progress becomes difficult or impossible, though probably this could be overcome by the use of carbon dioxide

VI

The claim has been made that by the use of carbon dioxide to increase lung ventilation after anaesthesia the respiratory complications which have been too common in the past can with certainty be entirely eliminated Like wise it is stated by some that by the routine use of intra venous glucose vomiting after anaesthesia, another of the bugbears of the past, has been abolished

Though both claims may appear somewhat exaggerated they are doubtless well founded, and the more extensive use of both treatments would appear desirable Carbon dioxide particularly might be more widely employed, since apparatus is available which renders its administration in suitable mixtures automatic, and which could safely be used in the wards by ordinary nurses

VII

Perhaps the most serious failing in our anaesthetic procedures is the fact that in spite of the frequent, or rather continuous, discussions as to the merits of various methods, no real attempt has ever been made so far as I know to investigate this problem in the only place and way in which it could be effectively done—that is, by observation of a large number of cases operated on with different anaesthetics but under otherwise similar conditions

A striking example of this neglect was provided some few years ago when workers at a large teaching hospital, in an attempt to improve on ether and to reduce its after effects, introduced an artificially impure ether as a new anaesthetic Though the conditions were ideal for a proper investigation, since large numbers of operations were done by the same men under conditions identical but for the anaesthetic used, yet no attempt was made to carry one out, and the numbers of cases reported by the partisans of rival methods were too small to be convincing Eventually the manufacture of the product ceased, and there may be many here who have never heard of it

Further, more recent examples might be quoted—such as spinal analgesia with percaine, which has been accused of causing an undue incidence of severe headache as compared with other agents, or the various barbituric acid deriva tives To base a comparison between three of these drugs upon an experience of 262 cases with one and of 23 and 15 with the others, seems to show a certain lack of sense of proportion to which medical men would sometimes appear particularly liable, unless indeed the results with the smaller numbers were uniformly and convincingly disas trous I must plead guilty to the same crime myself, for I drew some conclusions as to the value of ethylene without control records of nitrous oxide cases This series was begun, but was given up owing to the difficulty of collect ing enough material while working single handed in various scattered places

Inhalation anaesthesia, however, is largely a personal matter and is more of an art than a science, and whatever method is adopted by a skilled administrator and used consistently, the results will be apparently the same in most cases hence the wide diversity of agents apparatus and methods This apparent similarity might be dispelled were adequate data available for the various methods, and in any case it does not apply to the large category of poor risks, in which the choice of anaesthetic may make a large difference in prognosis

If what are sometimes regarded as special methods, such as gas oxygen or spinal, are reserved for desperate cases,

not only is insufficient practice obtained with them to obtain the best results but they may come into disrepute owing to the high mortality apparently resulting.

Reasons for Shortcomings

Such then are, in brief, the shortcomings, real or imagined, of our anaesthetic procedure, but before considering remedies it is necessary to investigate the causes.

These fall into two main categories, traditional and economic, which affect both institutions and individuals. The force of habit, custom, or tradition is fairly strong in most of us, and we probably find it easier to go on doing things in the same way when a good procedure is established. Further, there may be strong national traditions, as, for example, the use of chloroform in Scotland, which we are told was until recently almost universal; or local ones, as a result of which one method may be taught and used almost to the exclusion of all others. Hospital routine or tradition may be reinforced by the conservatism of theatre sisters and nurses, which though it may appear unimportant, can yet provide an effective opposition or a damaging passive resistance. Surgeons, again, who have operated with ease and success for a number of years are naturally prone to look askance at new methods, which may not give the same ease of access as the accustomed one, and may at first take longer in induction. The tradition of haste and hurry which still overshadows some of our theatres is in part a relic of the old pre-anaesthetic days when speed was essential, and in part the result of present economic conditions.

Hospital finances are not as a rule too secure, and committees and secretaries naturally hesitate to order new and possibly expensive machines which may not show any apparent benefit and may be discarded after a few years with the change of fashions or of medical staff. The latter, again, are not likely to be unanimous in their needs, and this may lead to unnecessary reduplication of apparatus.

As we know, the financial position of the individual anaesthetist is in most cases more precarious even than that of the hospitals, if such a thing is conceivable, and the same considerations as to apparatus apply even more strongly to him. His troubles are complicated by the fact that his private work, from which his living is derived, is carried out in nursing homes scattered over a possibly wide area and quite devoid of equipment, even perhaps without a lift. Obviously, such conditions tend to portability and simplicity or crudity of apparatus, and do not favour gas-oxygen.

Hospital practice, which may form the great bulk of his work, is almost entirely unremunerative, though the extension of the system of paying beds may alter this. Though many hospitals when advertising for anaesthetists insist that these should be specialists and not engaged in general practice, yet the possession of such an appointment does not guarantee any financial return whatever. It is therefore hardly surprising if anaesthetists limit their hospital attendances to their specified operation days, and show little inclination to embark upon extensive researches, while on these days conditions seldom favour new or experimental work.

Remedies Proposed

If progress is to be achieved it must be through the recognition by all concerned in the work of operative surgery, of the importance of anaesthesia as a subject, and of the fact that its technique is not necessarily perfect and stabilized. The status of our subject must be maintained and improved, and in at least one respect—that is, the time factor—it must take precedence in the theatre; for whatever anaesthetic procedure is adopted it must be completed before the operative procedure is begun. In another respect there is at times room for improvement, and that is in the standard of asepsis, which must be as rigid as possible where spinal, intravenous or other injections are made.

In teaching hospitals at least some attempt should be made by classification and investigation of records to evaluate the advantages and assess the risks of the various methods. This could well be done in the Surgical Units, where conditions should be more favourable, and where an additional anaesthetic assistant might be appointed.

The position of the anaesthetist as a specialist must be made secure and his services fully utilized in both "normal" and difficult cases, while the question of remuneration for hospital services needs to be considered.

Perhaps most important of all, the demon of hurry and hustle needs to be finally exorcized, and the tyranny of long lists broken.

INDICATIONS FOR PHRENIC AVULSION IN BRONCHIECTASIS

BY

W. G. OAKLEY, M.B., M.R.C.P.

Unilateral diaphragmatic paralysis by interruption of the corresponding phrenic nerve is the most recent of the principal methods of securing, by therapeutic collapse, that combination of rest and compression which plays so large a part in the successful treatment of chronic pulmonary diseases. With this object it may be used alone, or in conjunction with such methods as artificial pneumothorax, multiple intercostal neurectomy, and thoracoplasty.

The Radical Operation

The operative procedure now generally employed consists of avulsion or exairesis of the phrenic nerve through a small incision above the clavicle, for a distance sufficient to ensure breaking its connexion with the supra-pleural plexus and all accessory fibres. Although usually successful, this method has been known to fail in the production of a permanent paralysis, even after as much as seven inches of nerve have been avulsed.

Partial Operations

In addition to these permanent methods a number of operations have been devised by which a temporary paralysis may be effected in order to permit of healing of a tuberculous lesion and of a subsequent return of function of the diaphragm. These methods include crushing, freezing, alcohol injection, and section with immediate suture of the nerve, and are generally considered less satisfactory than the permanent operations. In bilateral basal bronchiectasis, however, the crushing operation has been successfully combined with phrenic avulsion in America by Matson in the following way. The phrenic nerve is crushed on the worse side, and the effect of a temporary paralysis on cough and sputum observed. If satisfactory improvement results, then the opposite nerve is crushed or avulsed, and the paralysis is thus made permanent.

Complications of Radical Operation

The complications of the radical operation are more formidable in theory than in practice, and fall into three main groups: (*a*) those due to failure in technique; (*b*) those due to adhesions in the course of the nerve; and (*c*) reflex disturbances.

In the first group haemorrhage constitutes the most frequent and serious of all complications, and results from injury either to the pericardio-phrenic artery that accompanies the nerve and venae comites in the same

sheath) or to the subclavian vein. The former is readily controlled, and never fatal; the latter is far more serious, and has been responsible for the majority of the very few deaths that have been reported. The vein may be torn as the result of tension on the sling formed by the phrenic and accessory phrenic nerves, which pass respectively behind and in front of the vein; the accessory nerve, however, almost always breaks first. The rarity of haemorrhage is shown by the fact that in Felix's series of 150 cases treated at Munich it occurred but once, and not at all in 300 cases reported by Welles at Saranac Lake. Air embolism is said to be more common in phrenicotomy than in phrenic avulsion, but can be avoided by prompt and careful arrest of haemorrhage. Section of the vagus has been reported in four patients, all of whom died.

The nature of the complication in the second group depends upon the structure to which the nerve is adherent, and varies from slight haemoptysis (when infiltrated lung tissue is unduly stretched) to cold abscess formation, pneumo- and pyopneumo-thorax, and even to fatal mediastinitis when caseous foci are opened up. The presence of a tuberculous empyema, and of pleural adhesions over the nerve, are considered by Sauerbruch and others as definite contraindications to avulsion.

Reflex disturbances are cardiac and respiratory, and probably owe their origin to interference with the vagus and intercostal nerves. They are usually slight and transient in nature, consisting of tachycardia, alterations in pulse volume, and dyspnoea.

Sequels

The sequels are insignificant and of short duration, consisting most commonly of pain in the corresponding shoulder, and more rarely of tachycardia, dyspnoea, and digestive upsets, which are as rare on the left side as on the right. In two cases reported by Yates spontaneous pneumothorax occurred on the opposite side, due possibly to the production of some slight contralateral emphysema.

PHYSIOLOGY OF THE DIAPHRAGM: THE EFFECT OF HEMI-PARALYSIS

Before considering the therapeutic application of phrenic avulsion it is important to review the normal respiratory function of the diaphragm and the physiological effects of paralysis of one or both domes, since on these follow, to some extent, the uses and limitations of this method of treatment. In man one-third of the total air inspired is due to the action of the diaphragm in keeping the lower lobes fully expanded, and the basal collapse which results from its paralysis is brought about by the unopposed action of the abdominal muscles. Phrenic avulsion affects primarily the position, movement, and structure of the corresponding half of the diaphragm, and thereby, secondarily, the thorax and its contents. The paralysis induced is strictly unilateral, and is evidenced by an immediate and progressive rise of the dome, which, in the course of three to six months, undergoes complete atrophy and is converted into a thin parchment-like structure. There are two principal forces acting on the paralysed dome to produce this rise: (*a*) the upward pressure of the abdominal contents; (*b*) the intrathoracic pull due to the natural retraction of elastic tissue in the lung, and to the contraction of the abnormal fibrous tissue. The second force may act over a long period, especially in cases of pulmonary tuberculosis, from a case of which Matson obtained the following figures: rise at operation, 3 cm.; rise one year after operation, 9.5 cm.; rise two years after operation, 13 cm.

The rise obtained depends on the side affected, the presence and extent of adhesions (especially in the costo-phrenic angle), and on the consistency of the overlying structure. The upward pressure of the liver on the right, and the interference of the heart on the left, are together held responsible for a difference of about two centimetres between the average figures quoted for the two sides: rise on the right side, 5 to 7 cm.; rise on the left side, 3 to 5 cm. The presence of fluid or of a resistant fibrous lower lobe may greatly reduce these figures.

When the full expiratory position has been reached, any movements exhibited by the paralysed muscle are usually paradoxical in nature, and best recognized by Bittorf's method of attempted inspiration with closed mouth and nose.

The effect of phrenic avulsion on the thorax is to decrease the capacity of the corresponding lung by one-fourth to one-third, or on the right side by four to eight hundred cubic centimetres (Brunner).

Goetze stated that a successful phrenicotomy is as good as a pneumothorax, and this may be true in those cases where a very high rise takes place. This reduction in lung capacity is not sufficient to produce dyspnoea in any but advanced cases of bilateral disease, and, for reasons given below, phrenic avulsion more often relieves than produces this symptom. Even in the few cases of bilateral paralysis reported in man there is the same absence of respiratory embarrassment that was noted by Lemon in experiments on dogs.

The chief intrathoracic structures affected by this sequence of events are the lungs and the heart, the latter being displaced upwards in left-sided paralysis sufficiently to relieve, in some cases, the palpitations and tachycardia which result from the drag of pleural adhesions.

The effects produced on the lung itself are therapeutically by far the most important, and consist of partial compression and relaxation, with the addition of rest, consequent upon the removal of the forces exerted upon it by the contractions of the diaphragm. While the truth of this general statement is accepted, there remains some disagreement about the extent of the lung tissue thus affected, and consequently, from the point of view of localization of the lesion, on the type of case in which phrenic avulsion is most indicated. Some observers limit the effect to the lower lobe, while others claim that the effect on the apex is as great as on the middle and lower lobes, in that the diaphragm exercises an equal pull on any part where there is a counter-pull.

Effect of the Type of Lesion

These divergent opinions suggest that, in addition to, and probably more important than, localization, there is some intrinsic property of the lesion upon which depends the success of treatment by phrenic avulsion. The capacity for spontaneous retraction and collapse being in theory a lesion's most essential property in this or any other form of collapse therapy, better results should be expected in the proliferative or productive than in the exudative type of pulmonary tuberculosis. Alexander and others have found in practice that this property is of more importance than the position of the lesion, and that if present in an otherwise suitable case, not only are the results good, but are in some measure proportional to the degree of collapse and compression obtained.

In bronchiectasis, however, this process of spontaneous retraction is so often responsible for the production and progression of the lesion that the results of phrenic avulsion must therefore depend upon its success in actively collapsing and compressing the dilated bronchi. Now it is obvious that active compression in diaphragmatic paralysis is greatest at the base, and, in the presence of dilated bronchi and pulmonary fibrosis in this position, will become increasingly less as the apex is approached. The position and extent of the lesion, therefore, together with the degree of rise of diaphragm obtained, are likely to be the most important factors in the treatment of bronchiectasis by phrenic avulsion.

Indications for Phrenic Avulsion

Before it is decided whether this supposition is supported by the clinical findings in the cases reported, the general indications for diaphragmatic paralysis in chronic pulmonary disease will be briefly classified. The indications may be considered under the two main headings of tuberculous and non-tuberculous disease.

Tuberculous Disease

1. Definitely basal lesions ; here phrenicotomy has its most consistently successful results in tuberculosis.

2. Unilateral disease in which sanatorium treatment alone is insufficient, and artificial pneumothorax, though indicated, because of adhesions or for social reasons, is not possible.

3. In chronic cases where artificial pneumothorax is impossible and thoracoplasty in contraindicated, phrenic avulsion on the worse side may cause great improvement, especially if the lesion is of the proliferative type.

4. Combined with artificial pneumothorax for one or more of the following reasons: (*a*) basal adhesions ; (*b*) to assist re-expansion ; (*c*) to prolong the interval between refills and lessen the incidence and amount of effusion and mediastinal displacement.

5. As a preliminary to thoracoplasty: (*a*) to remove, if possible, the need for thoracoplasty ; (*b*) to make thoracoplasty possible by improving the patient's condition ; (*c*) to test the opposite lung ; (*d*) to assist by collapsing the base of the lung, or, in tuberculous empyema, by decreasing the size of the cavity ; (*e*) to prevent aspiration to the lower lobe.

6. As symptomatic treatment to relieve: (*a*) cough and vomiting ; (*b*) copious expectoration ; (*c*) haemoptysis ; (*d*) dyspnoea ; (*e*) pleural pain ; (*f*) persistent hiccup ; (*g*) tachycardia and palpitations resulting from cardiac embarrassment ; (*h*) pyrexia.

Non-tuberculous Disease

1. Bronchiectasis.

2. In unresolved pneumonia as prophylaxis against bronchiectasis.

3. Subacute and chronic pulmonary abscess.

4. Hydatid disease of the lung.

Bronchiectasis

As a therapeutic measure in bronchiectasis phrenic avulsion has received less attention than in tuberculosis, and consequently the literature contains fewer opinions on its uses and limitations. The results obtained in bronchiectasis by this form of treatment, and consequently the conclusions arrived at, agree no better than those reported in connexion with pulmonary tuberculosis, and suggest that the indications for phrenic avulsion in the former disease are not fully realized or understood.

The following series of cases, collected over a period of three years at St. Bartholomew's Hospital, have been followed up and analysed to discover, if possible, the indications and contraindications for phrenic avulsion in bronchiectasis.

Clinical Observations.—Seventeen cases are reported, in all of which the diagnosis of bronchiectasis was based on clinical and *x*-ray findings, lipiodol being used in almost every instance. The original lesions responsible for the bronchiectasis were traced wherever possible, and found to comprise the following conditions: pneumonia, 9 ; "influenza," 1 ; foreign body, 1 ; *x*-ray treatment for carcinoma of breast, 1 ; new growth, 2 ; unknown, 3. The operation was carried out nine times on the left side and eight times on the right, paralysis of the corresponding dome being observed by *x* ray in every case. The technique employed was that of avulsion of the nerve, or, failing this, of radical excision.

Complications.—Pain in the corresponding shoulder occurred in about half the cases. Section of the thoracic duct occurred once, and was followed by a chylous discharge of short duration. Serious haemorrhage was entirely absent from this series.

Previous Treatment.—In four cases artificial pneumothorax was attempted, but prevented by adhesions in all but one, in which it was successful in relieving the cough. As soon, however, as the air was absorbed the cough returned, and necessitated a subsequent phrenic avulsion. Creosote baths were unsuccessful in the few cases in which they were tried. Postural drainage was employed before operation in all cases with much sputum

Results in Cases Treated

The results in the seventeen cases of bronchiectasis may be summarized under three headings: (1) those in which the symptoms were completely relieved ; (2) those in which improvement was being maintained when the patient was last seen ; (3) those in which temporary improvement was followed by relapse.

The first group contains four cases which deserve brief mention.

In Case 1 a phrenic avulsion was performed without success on a man who had a persistent distressing cough with copious foul sputum. Five months later a collar stud was removed from the left lung through a bronchoscope, and a complete cure resulted in a few months. In view of the very advanced cavitation of the left lower lobe, demonstrated by lipiodol *x* ray, it is reasonable to suppose that the phrenic avulsion, by assisting in the obliteration of the cavities, was in part responsible for the rapid cure.

Case 2, a girl aged 20, with left-sided bronchiectasis following pneumonia in infancy, was treated by paravertebral thoracoplasty in August, 1926, with great success. Five months later the patient still had a cough, with greatly diminished sputum (1,200 c.cm. to 60 c.cm. per diem), and a left phrenic avulsion was therefore performed, since which there has been complete relief of symptoms. Here the usual sequence was reversed, but the value of diaphragmatic paralysis as a complement to thoracoplasty is well illustrated.

In Cases 3 and 4 no other treatment contributed to the success of phrenic avulsion. In the former, that of a girl aged 15, the only symptom was cough, which was persistent and dry. *Lipiodol x ray* showed dilatation of the left lower lobe. Phrenic avulsion was followed by disappearance of the cough, which has not returned.

The last case of so-called "cure" was that of a boy, aged 14, with a history of broncho-pneumonia when 4, followed three years later by two separate large haemoptyses. Vaccine treatment was carried out at a sanatorium for two years, and the boy remained quite well until, at the age of 14, he developed a cough, with much sputum. Lipiodol *x* ray showed basal bronchiectasis, and phrenic avulsion was performed in June, 1927. There was an immediate decrease in cough and sputum, which fell from over 200 c.cm. of muco-pus to about 5 c.cm. of clear mucoid secretion daily. Nine months later he was symptom-free, and is now able to swim and play football without cough or shortness of breath. There has been no further haemoptysis.

It is important to observe that in these four cases the lesion was not only basal, but completely confined to the side on which phrenic avulsion was performed, a combination of characteristics not to be found in any of the cases of improvement now to be considered.

The second group contains seven cases in which there has been lasting improvement in general conditions and weight, in addition to reduction or disappearance of cough or sputum. In six cases the condition of the patient is stationary, while the seventh and most recent of the series has been improving ever since his operation five months ago. Four cases gave a history of pneumonia

Summary of Results of Seventeen Cases of Bronchiectasis treated at St Bartholomew's Hospital by Diaphragmatic Paralysis between 1927 and 1930

one of x ray treatment following removal of the left breast for carcinoma, and in two no cause could be traced. The maximum daily sputum before operation was 200 c.cm., and after operation 25 c.cm. In two cases sputum has disappeared altogether, in four it has decreased in amount, and in one it has remained the same. In all seven cases cough is still present, but improved, and up to date there has been no recurrence of haemoptysis in the three cases in which it had occurred before operation. In this group the disease in three cases was completely unilateral but very extensive, involving both upper and lower lobes. Two cases showed x ray evidence of involvement of the opposite base, and in the remaining two moist added sounds were persistently audible in the same situation.

The third group contains six cases in which temporary improvement was followed by relapse. The symptoms in two cases were subsequently found to be due to new growth of the lung, which proved fatal shortly after the operation. Quite remarkable improvement followed phrenic avulsion in two cases with much sputum. In one the sputum was reduced from 1,200 c.cm. to 120 c.cm., and thoracoplasty, though indicated on account of the extent of the lesion, was unfortunately refused. In the second case both cough and sputum rapidly disappeared, but recurred after a short interval. Here, again, the lesion involved the whole of one side, retention of secretions causing pain over the upper lobe, which was relieved by postural drainage. The remaining two cases showed a slight but definite improvement, consisting in the one of reduction of cough, and in the other of decrease in sputum. A subsequent thoracoplasty was intended in one case, but had not been performed when the patient was last heard of six months ago. In both these cases not only were there bilateral basal lesions, but the mid zones were also involved, and in one there was evidence before operation of collapse of the corresponding base.

Summary of Results

In the seventeen cases of bronchiectasis phrenic avulsion gave the following results:

	Cases	Percentage
Complete relief of symptoms	4	24·5
Lasting improvement	7	41·0
Temporary improvement with relapse	6	35·5

Conclusions

1. Phrenic avulsion in experienced hands is a safe operation, and the complications are more to be feared in theory than in practice.

2. Only in strictly basal and unilateral cases of bronchiectasis can phrenic avulsion be reasonably expected completely to relieve the symptoms.

3. Improvement is to be expected in unilateral bronchiectasis in which the lesions are confined to the bases and not advanced on the better side.

4. In unilateral bronchiectasis in which the lesion extends into upper or mid zones, temporary improvement *is the rule, but relapse must* be expected unless thoracoplasty is performed.

5. In bilateral basal bronchiectasis with lesions in upper or mid zones, little benefit is to be hoped for from unilateral diaphragmatic paralysis.

6. As a preliminary to thoracoplasty phrenic avulsion should always be performed, but should not be allowed to shelve the larger operation in event of a brilliant but temporary cure.

For permission to record the cases described I am indebted to the physicians and surgeons under whose care they were admitted to hospital, and particularly to Mr. J. E. H. *Roberts, who performed the great majority of the operations.*

INFANTILE DIARRHOEA*

BY

A. V. NEALE, M.D., M.R.C.P.

PHYSICIAN TO OUT-PATIENTS, CHILDREN'S HOSPITAL, BIRMINGHAM

Judged from the available statistical reports[1] on fatal diarrhoea in infants, the incidence has fallen considerably. In 1905 in England and Wales the death rate in diarrhoea and enteritis in infants aged from three to twelve months was 62. In 1928 the same record shows a rate of only 23, and it would appear that the overcrowded areas of the big cities are largely responsible at present, the relative rates from infantile diarrhoea in Birmingham[2] being 26.5 in the crowded central wards and only 8.5 in the outer wards. Thus from the public health aspect much has been achieved by way of improving the general hygienic factors concerned in the problem—more particularly regarding regulations of better and cleaner food supplies, especially in the case of milk. Certain uncontrollable factors, however, periodically cause great fluctuations in the incidence of diarrhoeal disease—for instance, the abnormally hot dry summer of 1921.

Clinically diarrhoea in the infant is a common and frequently a most important sign of ill-health. The complex functions of the alimentary tract are easily thrown out of rhythm by a wide variety of causes, some apparently trivial, others grave in themselves. Physiologically the infant's alimentary tract is only capable of dealing with a narrow range of food; hence nature's arrangement for a nearly complete food in one medium—milk.

Clinically we recognize certain principal causes operating in infantile diarrhoea, such as abnormal reactions to food; irritants, bacterial or chemical, ingested with food; irritants produced in the bowel by fermentative changes; specific enteral infections and parenteral infections generally. Excessive carbohydrates or fat is sometimes responsible alone, but intolerance to protein is extremely rare, and the probable reasons for this I will note later.

Of the specific infections of the alimentary tract causing acute diarrhoea in infancy, dysentery bacilli (Sonne and Flexner varieties), and typical and atypical forms of the paratyphoid bacilli are not infrequently responsible, and specific agglutinins may be detected in the blood afterwards.

Various strains of streptococci and the pneumococci are recognizable in some outbreaks. A period of acute diarrhoea is frequently seen at the commencement of an acute exanthem, often, in fact, several days before any other clinical features appear, this being a good illustration of the ease with which the alimentary functioning in the infant is disturbed. Outbreaks of summer diarrhoea may or may not have a recognizable bacterial cause, but several factors in the environment are related, atmospheric humidity and temperature being foremost. The prolonged hot dry summer of 1921 was coincident with a great rise in the incidence of infantile diarrhoea. Blackfan's (Boston) investigations on humidity and temperature in large room-incubators have shown that there is definitely an optimum level for the well-being of the infant, and any rapid or marked variations in the temperature and moisture in the air frequently cause outbreaks of diarrhoea.

Certain physiological conditions which are peculiar to the normal infant have been demonstrated by Klumpp and Neale.[3] The normal reactions of the contents of the small intestines is slightly acidic—*p*H 6.5—and probably any great change is not tolerated. The gastric secretion in the infant is remarkably small, and any infection or minor disturbance is often accompanied by a rapid and complete diminution of the gastric secretions. The enzymes in the pancreatic secretion are present in such small quantity as to be easily minimized below a functionable level, this being specially so concerning the lipase and amylase which are in low concentration during the first year of life. The trypsin ferment, however, is always, from the earliest days of life, present at a high level. These facts may be linked with the rapid intolerance to carbohydrate and fat in the acute enteral dysfunctions of infancy. The ease with which such food substances, which would normally be digested and absorbed, fail to be digested and utilized, may explain many of the parenteral causes of diarrhoea. Pyrexial and infective disorders no doubt adversely affect the digestive ferments and render the food material in the intestine ready prey for putrefactive bacteria, with the result that a highly toxic pabulum replaces the normal healthy contents. Infants vary considerably in their susceptibility to minor intestinal physiological variations—for instance, as seen in the ease with which the so-called "catarrhal" or the "eczema" individual develops diarrhoea. Deficiency in vitamins—more especially in A and B—renders the alimentary tract unstable, and diminishes local resistance to infection.

EFFECTS OF DIARRHOEA

The rapid depletion of tissue fluids is remarkable in infantile diarrhoea, and loss of the normal intestinal secretions is a serious matter to the infant. Ketosis, together with disturbance in the acid-base equilibrium, is soon effected, and a variable degree of acidaemia or alkalaemia occurs. General disturbance of tissue functions ensues, and soon the whole illness may assume much greater import through the secondary effects of the diarrhoea. The delicate protective mechanisms in the bowel are quickly removed, and, by absorption, highly toxic or bacterial or undigested food products may enter the body. Secondary bacterial infections of the bowel may supervene which render matters worse. The absorption of undigested protein substances through the damaged bowel may be responsible for some of the clinical features of the acute intestinal intoxication and anaphylactic phenomena seen, and such may be the explanation of certain cases of protein sensitization producing allergic states in children. Renal and hepatic functions are often seriously disturbed by the dehydration and intoxication, and in fatal cases necropsy reveals evident acute degenerative changes in the parenchymal cells. Failure of the functions of these important organs may directly determine a fatal issue. The myocardium similarly shows the general toxic effect, tachycardia and sometimes unusual rhythm appearing. The marked apathy and the depression of the normal reactive state of the infant indicates the damage to the nervous system, and in severe cases coma may supervene.

CLINICAL VARIETIES

Acute ileo-colitis has a characteristic sudden onset with diarrhoea with or without vomiting. The stools are very frequent, mucus and blood being visible usually. Clinical evidence of abdominal pain and tenesmus is present. The temperature is not usually much raised, but a rapid pulse is a feature and acute severe toxaemia is evident. The usual cause of this type of disease is the dysentery group of bacilli, particularly of the Flexner or Sonne varieties, and occasionally coliform bacilli, resembling but not identical with the paratyphoid group, are present, the latter being probably not at all uncommon infecting microbes in infants and children as judged by routine bacteriological examination of the stools and agglutination tests in the blood. The

* Read in opening a discussion in the Section of Pathology and Biochemistry at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

disease is due to a local infection of the bowel and absorption of the powerful bacillary toxins into the circulation. The local intestinal damage varies from simple acute catarrhal changes to a diphtheritic form of necrosis of the mucosa, but even in the very serious cases remarkably little damage may be visible when the bowel is seen.

Fermentative diarrhoea is associated with acidic, gaseous, frothy, highly irritating, offensive stools causing troublesome excoriation of the skin; gaseous distension of the bowel is evident, and powerful peristaltic movements may be seen preceding the explosive passage of stools. Dehydration is sometimes extreme and becomes a very serious matter. Pyrexial reaction may be minimal or absent or even subnormal. The infant is essentially suffering from starvation, dehydration and much physical discomfort. The intestinal fermentation may arise from irregular feeding or overfeeding with carbohydrates and fats, or may be directly due to a temporary depletion of the normal digestive enzymes as occurs in a parenteral infection. Associated septic and oïdial infections in the mouth are commonly seen. There is a gross disorder of the alimentary physiology affecting equally its digestive, defensive and motility functions.

Acute alimentary intoxication is a serious disorder which may arise from the ingestion of bacterial or chemical toxic material or occurs as a result of absorption of decomposition products from intestinal fermentation. It may seriously aggravate the clinical course in simple fermentative diarrhoea. Very severe diarrhoea with watery stools, vomiting, marked general collapse, subnormal temperature, rapid feeble pulse, scanty urine, clammy skin, pallor, and sighing respiration is the more typical clinical picture. Convulsive movements may appear and terminate the scene. Many of the characters of this illness strongly suggest acute anaphylactic shock, and in great probability the cause is of this nature. Boyd[4] has demonstrated the presence of highly toxic substances in the bowel of this type of case, and portal blood from patients contained the toxic material. Dehydration rendered experimental animals much more susceptible to the toxic substances. Frequently surprisingly little morbid anatomical changes can be seen in the bowel in acute intestinal intoxication with severe diarrhoea (cholera infantum), but intense degeneration is evident in the kidneys and liver, and occasionally suprarenal haemorrhage is present.

DIAGNOSIS

An accurate history of the diarrhoeal disorder, including information concerning the qualitative and quantitative feeding, is helpful. By careful examination of the stools much useful information can be obtained. Pyrexia and tachycardia are indications of an infective origin. Rapid anaemia, with occasionally purpura and a variable degree of cyanosis, are signs of the toxaemia. Depression of the fontanelle, dry inelastic skin, sunken eyes, rapid loss in weight and small urinary secretion denote at a glance the degree of dehydration. Excoriation of the buttocks indicates a diarrhoea of some duration. Careful and complete examinations of the infant must be made to determine parenteral infections of all types. Meningismus may appear and acute pyelitis and cystitis may be recognized as a cause or effect of the enteral disease. An acute intussusception may arise due to the irregular intestinal movements.

TREATMENT

The profound and complex upset of tissue metabolism consequent upon the dehydration, ketosis and toxaemia renders the treatment of infantile diarrhoea a matter of urgency. First-class nursing attention is essential, and the child must be handled with meticulous care. Fluids must be introduced into the body to replace the excessive loss occurring. In a mild case all milk should be stopped for twenty-four hours and replaced by the use of pure water, quarter strength physiological saline, weak tea. Ringer's solution of 2 per cent. pure glucose solution by this route is indicated. All these substances require no digestion and are absorbed rapidly in the upper part of the small bowel, thus affording rest to the lower. Gentle rectal lavage with warm saline during this period will relieve gaseous distension and afford comfort to the patient. In severe cases, especially with associated vomiting, sterile fluids must be given by parenteral routes. Rest to the alimentary tract and the injection of fluids parenterally allays the diarrhoea and lessens the tissue dehydration, and affords establishment of normal kidney and hepatic function to aid in the detoxicating and eliminative processes.

Overcoming the problem of conveying water and glucose to the blood and the tissues plays a great part in the therapy. Water is the drug, *par excellence*, in these disorders. Sterile pure saline can be introduced into the lax subcutaneous tissues in the proportion of about 10 c.cm. per pound of body weight once or twice during twenty-four hours. In expert hands it is a simple matter to introduce, by slow injection, 5 per cent. glucose solution into the superior longitudinal sinus at the anterior fontanelle, or in some cases it may be more convenient to inject the fluid into the internal saphenous vein. Intraperitoneal injection of saline or glucose solution is a useful method also. The methods may be combined in individual cases. It is a matter of vast importance to use perfectly freshly made pure glucose solution for these procedures. Blood transfusion is an invaluable measure in some cases and often seems to determine the recovery of the most serious clinical case of infantile diarrhoea and dehydration. Whole blood from a suitable donor is given, 15 c.cm. per pound of body weight being a useful guide, but slow introduction to the longitudinal sinus or a vein is essential, as too rapid injection may cause over-distension over the right side of the heart.

A matter of some importance, often overlooked, is the loss of protein contained in the fluid escaping from the body by way of the intestine, even in stools in which blood is not detectable. The efficiency of blood transfusion may have a relationship to this.

Parenteral infection must be dealt with, and everything done to check the infection. Pus should be evacuated where possible. Anti-dysentery serum given intramuscularly is efficacious in some cases of acute dysenteric ileocolitis.

The use of drugs forms a very small part in the management of infantile diarrhoea. Morphine is dangerous, but small doses of belladonna may be used to check intestinal spasm and pain. On account of the ease with which the body temperature is affected in the infant a warm room with average humidity is a point of importance. In some severe cases the thermo-regulatory mechanism appears to be thrown out of gear, and in such instances the placing of the infant in an open self-regulating warm incubator of the "Hess" type is of distinct value. Since the return of intestinal digestive power is probably slow, the diet in the recovery stages must be very carefully controlled—always remembering that protein is probably the most easily digested and fat the least so at this age. Breast milk if available at this stage is of high value. Easily assimilable forms of carbohydrates, as pure glucose or dextro-maltose preparations, and buttermilk foods are usually satisfactory until the child gradually reassumes tolerance to a more full and varied diet.

We see, therefore, in the study of infantile diarrhoea, many problems concerning disturbances of the intricate physiology and biochemistry of the tissues, and how a

knowledge of these changes, however meagre such may be at present, controls and guides us in the treatment of this common but really complex disorder in infancy.

AN ATROPINE TEST IN ASTHMA

BY

MARJORIE GILLESPIE, M.D.Glas.*
(From the Department of Physiology, King's College, London)

Among the drugs used in the treatment of asthma, atropine has always held a prominent place, but its therapeutical value has been found to be much less constant than that of adrenaline. Atropine acts, presumably, by paralysing the nerve endings of the vagus, and so preventing stimuli from the vagus centre reaching the bronchial muscle. Broncho-constriction has been shown to result from stimulation of the upper respiratory tract—that is, reflex stimulation of the bronchial muscle through the vagus centre. In many cases of asthma the treatment of nasal abnormalities has been sufficient to abolish attacks, which would suggest that these attacks were of "nervous" origin. It is also acknowledged that psychical stimuli in some patients play a considerable part in inaugurating a spasm. Since atropine prevents nervous stimuli from reaching the bronchial muscle, it has been thought that it might be used to differentiate between broncho-constriction due to reflex stimulation of the vagus and that due to direct stimulation of the bronchial muscle—that is, between nervous and chemical stimulation.

By using the method introduced by McDowall and Thornton (1930) for recording the movements of the isolated bronchi, it has been shown that contraction of the bronchial muscle follows the injection of pilocarpine, and that a small dose of atropine immediately after produces complete dilatation. A second dose of pilocarpine now produces no result, but a very small dose of histamine still causes the muscle to contract. Histamine is supposed to act directly on muscle, while pilocarpine acts through the nerve endings. Similar contractions are obtained by injecting other substances known to act directly on the muscle. The amount of atropine injected was small (*0.13 mg.*), as larger doses may paralyse the muscle itself.

The usual method of administering atropine in asthma is as tincture of belladonna in a mixture to be taken by the mouth, but the unpleasant dryness of the mucous membranes and the effect on the pupil prevent its continuous use. As a method of estimating the part played by nervous stimuli in inaugurating broncho-spasm, a full dose of atropine might be injected subcutaneously at the onset of an attack. In those cases where contraction of the bronchial muscle is due to direct chemical stimulation of the muscle, atropine would be expected to have no effect, whereas in the truly nervous type the attack would be aborted. In this way the patients whose attacks are due to psychical stimuli alone could be differentiated from those who owe their symptoms to a fundamental chemical alteration of the blood.

I wish to express my thanks to Professor R. J. S. McDowall, who suggested this method of differentiation.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

FOUR GENERATIONS OF HETEROSEXUAL TWINS WITH PREPARTUM AMENORRHOEA IN TWO GENERATIONS

The genealogical tree shown below is that of a woman who was admitted to hospital on account of twin pregnancy and a mild degree of albuminuria. She was 22, and had never menstruated. Her twins were of opposite sex. Inquiry revealed that this was the fourth generation of heterosexual twins, and that the patient's mother had also had amenorrhoea up to the time of her first pregnancy at the age of 20.

I am indebted to Dr. C. J. Penny for permission to publish this case.

C. E. Taylor, M.A., M.R.C.S., L.R.C.P.
House-Physician, Royal Hants County Hospital.
Bromley, Kent.

BILATERAL HERPES ZOSTER

Since Darier has stated that herpes zoster is almost invariably unilateral (*Précis de Dermatologie*, 1918) and Sutton (*Diseases of the Skin*, 1928) makes the same observation, but notes that bilateral cases have been described by Fordyce (*Journ. Cut. Dis.*, 1915, 319) and Howard Fox (ibid., 1915, 492) this case which was recently under my care would seem worthy of publication.

A healthy man, aged 21, consulted me on June 15th, 1931. He stated that on June 12th he felt ill, had a sore throat and a headache, and thought that he had a temperature; as he felt no better on the following day he stayed in bed. On June 14th he had some pain behind the right ear, and later in the day noticed the eruption on account of which I was asked to see him. At this time there were well-marked herpetic vesicles on an area the size of a florin over the right parotid gland and over the outer surface of the pinna of the right ear; he had a temperature of 101° F. He was ordered to stay in bed, and was given sodium salicylate internally and a dusting powder for external application.

On June 17th typical lesions of herpes zoster appeared on a similar-sized area over the left parotid and over the outer and inner surfaces of the pinna of the left ear. During this time he complained of much pain behind both ears, and felt ill. The pains had ceased by June 19th, and the eruption was beginning to dry up. By June 22nd the eruption was disappearing, and he felt quite well.

In this case there was no associated facial paresis, such as is sometimes seen in cases with this distribution. There was no history of any contact with varicella, and the most probable source of the trouble would seem to have been the throat infection.

NORMAN BURGESS, M.A., M.D., M.R.C.P.,
Assistant Physician, Skin Department, Bristol General Hospital; Consulting Dermatologist, Bridgwater Hospital.

Reports of Societies

DISEASES CONVEYED BY MILK

At the forty-ninth annual congress of the National Veterinary Medical Association of Great Britain and Ireland, which was held at Norwich from August 22nd to 28th, Messrs. M'ALLAN and HOWIE of Aberdeen contributed a paper entitled "Milk hygiene," in which they considered the more important diseases carried to man by milk.

Undulant fever had recently been given great prominence, particularly as regards its association with animals. The organisms found in animals gave rise to symptoms in man which were so indefinite that differential diagnosis was almost impossible without the aid of serological methods. Failure in diagnosis probably accounted for the paucity of recorded cases in the past, since the disease was now being reported with comparative frequency from various countries. In Aberdeen seven definite cases had been recorded in the last two years during the routine examination of 250 blood samples sent in for the Widal test. The biological examination of milk in recent years had revealed that about 25 per cent. of cattle were infected in this country, yet the disease was relatively uncommon in man. On the Continent and in America the strain of organism most commonly found in man was the porcine, which was rare in Britain, and might account for the comparative immunity of human beings. One of the human cases in Aberdeen was traced to the milk of a cow which had been vaccinated with a porcine strain. Milk-borne salmonella infections were not common in this country, and were probably, in most cases, the result of human contamination; in some outbreaks, however, the disease appeared to originate with the cow, and three outbreaks were cited to illustrate this. In 1925 an outbreak involving 497 persons was traced to a single cow, the udder of which was infected with a strain of *B. enteritidis* in every way identical with that recovered from the patients. The second instance only involved nineteen persons, and was traced to an intestinal infection of the cow with the *B. enteritidis* of Gaertner. The milk had been contaminated by the faeces, and the outbreak disappeared with the removal of the infected cow. The third case, which was similar to the last, was due to the bacillus of Aertrycke.

Tuberculosis was undoubtedly the most important of the diseases carried by milk. In Scotland there was in progress an investigation into the numerical incidence of tubercle bacilli in milk, in which methods of sampling and laboratory technique were uniform for the four centres engaged in the inquiry. Each centre would examine 1,950 samples during a period of two years (650 samples of raw milk, 650 of pasteurized, and 650 of retailed milk). Results for the first six months indicated that the percentage of positive samples was likely to be greater than was generally accepted. Milk was most frequently infected directly from the udder, and the opinion was expressed that bacilli might be eliminated in the milk some time—perhaps several months—before any clinical evidence could be found in the udder. Even when this was present the discharge of organisms might be intermittent, and might even cease for a considerable period until a fresh focus of infection appeared. Frequent and thorough inspection was the only sure method of combating tuberculous mastitis. The bulk of this inspection had to be conducted when the cows were housed; they had to be examined shortly after milking, for it was a waste of time handling udders when they were partly full. Apart from the establishment of tubercle-free herds, the best method of control was regular clinical examination. These frequent visits had also an educative value, and promoted the control of other diseases also. Bulk biological testing was a valuable accessory method. Although cows were susceptible to the toxin of diphtheria, no true cases of udder infection had been reported. Infection of the milk was usually brought about by sores on the teats being infected by some farm worker who was either suffering from the disease or was a carrier. One such case was reported by the authors from Aberdeenshire.

Among the general measures necessary to ensure a healthy milk supply, it was urged that every encouragement should be given to the production of the highest grades of milk, and that all others should be pasteurized; for this purpose the need for efficient plant was stressed. The supply of cow's milk had never been so safe as it was to-day, but its increasing use as a food, especially for school children, should increase the demand for the best grades and lead to a general, if gradual, improvement.

Calcium and Phosphorus in Milk

Dr. R. G. LINTON discussed the calcium and phosphorus supply of dairy cows, and pointed out that there was a great difference between the modern dairy cow and the cow leading a natural life, grazing at large on suitable food. Normally a cow secreted some 200 gallons of milk for the sustenance of a calf; her food would be grass and various plants which were in their most nutritious state during the normal period of maximum milk yield. The modern cow produced at least four times this amount of milk, it bred at any seasonal period, and reached maturity at an unnaturally early age. Its food was mostly unnatural, and often unsuitable, and it was often badly housed and given insufficient water. Quantitatively its total nutriment had been adequately studied; but it was only in recent years that serious attention had been paid to the need for replacing the mineral constituents drained from the body into the milk. What this amounted to was easily determined, but its significance in relation to the health and well-being of the cow was not clear. There was no definite knowledge of the actual needs of the cow in respect of calcium and phosphorus, either for its body or for milk secretion.

Tuberculosis in Swine

Mr. D. J. ANTHONY, considering some common diseases of pigs, stated that the commonest was tuberculosis, about 9 per cent. of those coming under his attention being thus infected. In the majority the infection was localized in the submaxillary lymphatic glands, and in practically every infected pig the head and throat were affected. The disease was chiefly of bovine origin, resulting from feeding on milk and milk products. This accounted for about two-thirds of the cases, the remainder suffering from avian tuberculosis. Prevention consisted in the cooking of milk foods and the elimination of tuberculous poultry.

Reviews

QUANTITATIVE PHARMACOLOGY

Bioassays: A Handbook of Quantitative Pharmacology,[1] by J. C. MUNCH, is a large volume of nearly 1,000 pages, and is by far the most comprehensive work that has yet appeared on this comparatively new subject. The mere size of the book indicates that this branch of the science has already attained considerable development. Until the end of last century pharmacologists were concerned chiefly with the qualitative aspect of their work, but since then more and more attention has been directed to quantitative studies. Such studies have involved an immense amount of labour, the whole value of which depends on scrupulous attention to accuracy in detail. There was a risk that the subject would be overwhelmed by the mere mass of its literature. The author's object is to provide a guide to this literature. He explains in the preface that his own researches were handicapped by the absence of any critical compilation of general information about quantitative pharmacology, and he has aimed at providing an encyclopaedia of reference for those doing research in this subject. His task has been very heavy; he says that 17,000 references were consulted, and that citations from 5,000 of them are included in the text. Inspection of the volume shows that a very thorough search of the literature has been made, and the author's claim to have covered the literature up to January, 1930, appears to be justified. An outstanding feature is the wealth of tabular matter. This is a very important thing, for it is impossible to do justice to quantitative data without a liberal use of tables.

Dr. Munch has given an encyclopaedic rather than a critical account of his subject. Mention is made of all the quantitative work that has been done, not only the more important and outstanding investigations, but also what may be termed "second-class matter." From the point of view of reference this is a valuable feature, because the lesser known work is always the most difficult to trace. This catholic attitude has, however, the disadvantage that there is no very close relation between the importance of the work mentioned and the space devoted to it. The tragedy of quantitative research is that its value falls so heavily as soon as any new experimental error is demonstrated: one short paper may wipe out the value of volumes of past researches. Dr. Munch treats his subject in a roughly historical manner, and gives a full and interesting account of earlier investigations; but he does not always make it clear when that work is of historical interest only. His book will be of the greatest service to the specialists for whom it is primarily intended, but it may be found rather confusing by those not well versed in the newer pharmacology. A short chapter of 20 pages has been inserted dealing with experimental technique. This subject might well have been omitted as falling outside the scope of the book, but since it is included it should be treated more fully, because the value of any description of experimental technique depends entirely upon full and accurate detail. Modern pharmacology is concerned with small fractions of milligrams, and the letter γ is generally accepted as the sign for one-thousandth of a milligram, but the author uses the contraction μ mgm. This seems an unfortunate symbol to choose, since the letter μ usually stands for micro, which indicates one-millioneth, both in electrical units and in microscopical measurements.

As its title indicates, the volume deals with the measurement of drug action by means of animal experiment, though certain chemical tests are included. Chief attention is paid to those methods of bioassay which are required by the *United States Pharmacopoeia*. For example, digitalis and its allies occupy 150 pages, and references are given to 700 papers on the assay of these drugs. Accounts are also given of methods of biological measurement that have been either established or attempted in the case of a large number of substances other than those officially recognized. Apparently the author has confined his attention almost entirely to experiments on animals, and has not considered clinical work. This seems a pity, for in some cases (such as that of anthelmintics) comparative analyses of the actions of drugs on patients have been carried out with great accuracy on a very large scale, and with controls just as adequate as those employed in animal experiments.

The chief impressions that remain with us are surprise at the amount of investigation that has been done in the subject of quantitative pharmacology, and admiration for the author's industry in collecting this great mass of detailed information. The lack of any full volume of reference on this subject has in the past been a serious handicap to research workers, for without such a book it is really quicker to do a piece of work than to try to find it in the literature. The appearance of *Bioassays* will do much to lighten the task of those engaged in quantitative pharmacology.

THE MONGOL IN OUR MIDST

Dr. F. G. CROOKSHANK has restated his views on the origin of man in a much enlarged version of his book *The Mongol in Our Midst*.[2] Perhaps on account of the opposition his theory encountered, it is not surprising that the present work is more controversial in tone. This may indeed be necessary, but we doubt whether it is a gain either to the profit or pleasure of reading the book, for it involves a large amount of repetition, and one misses the direct appeal of the shorter vision.

As is well known, he has rehabilitated and extended Langdon-Down's ethnic classification of idiots and imbeciles. The original description of the mongolian idiot has become classic, but its anthropological significance has often been denied. Yet in view of the successive waves of Asiatic invasion that flooded the East, and sometimes even reached the middle of Europe, there must have been ample opportunity for a mongolian admixture to European blood, though it remained in the background until some evolutionary or developmental fault brought it to the front again. The author illustrates this by an interesting example unrelated to ordinary mongolism. It is recognized that the Lapps are a primitive mongolian race, whose physical characteristics were classed by Virchow as achondroplasic. Their women have small pelves and narrow acetebula. The heads of the femora of the non-mongolian Norwegians, on the other hand, are large. The offspring of mixed marriages between Lapps and Norwegians are specially liable to congenital dislocation of the hip, inheriting as they do a large head and a small socket for their thigh bones. In crossings, unfavourable variations may appear as easily as favourable ones. Dr. Crookshank holds, then, that the mongolian idiot is an atavism, and produces an astonishing number of observations to prove his point.

But he would go much further than this. He would take mongolism as merely an example of a much wider thesis. It has been almost tacitly assumed by anthropologists that man arose as a single shoot from a simian, or more probably pre-simian, ancestor. But is that

[2] *The Mongol in Our Midst*. By F. G. Crookshank, M.D., F.R.C.P. Third edition, greatly enlarged and entirely rewritten. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1931. (Pp. xv + 539; illustrated. 21s. net.)

assumption justified? Is not the existence of four different blood types, some incompatible with others, very suggestive of separate strains? Dr. Crookshank is struck by the close affinities between the three races of men—black, yellow, and white, and three races of apes—gorilla, orang, and chimpanzee. He infers a polygenetic origin for man, each of these races of men and of apes springing from a particular pre-simian ancestor. Thus, the negro and gorilla originated from one stem of the common ancestral stock of the Primates, the mongolian and the orang from the second, the "white" races and the chimpanzee from a third, and he considers that a study of prehistoric man supports this view, the Cro-Magnon being of the European, the Aurignacian of the mongolian, and the Neanderthal man of the negro type. It would not be surprising, in that case, for atavistic traits which had become recessive to emerge again in the event of an evolutionary failure, for "it is the dreaded law of inheritance that nothing is lost which once gains access to the circulating blood." He would agree with Sir Arthur Keith that the endocrine balance plays an important part in moulding racial characters, and finds this quite compatible with his own theories, since alike in the mongol, the mongoloid idiot, and the orang the thyroid gland is less active. Similarly, both in the negro and the gorilla the suprarenal is less active, while in the white races and the chimpanzee the pituitary is less active.

At least, that is the conclusion we draw from the earlier editions of Dr. Crookshank's book, and though it is less definitely stated in this edition, we take it this is still essentially the author's view. We are assured by certain anthropologists that there are great difficulties in the way of accepting it, but are there not also great difficulties in the way of the more orthodox views? Can all the mass of evidence that the author has collected be lightly brushed aside? We confess that to us it seems to demand most serious consideration.

"IMMUNO-SURGERY"

Under the title of *Immuno-Chirurgie*[3] G. DANIEL has collected all the various forms of specific immune therapy which are, or might be, of use in surgical practice. No doubt such a book would be of considerable service if due care were exercised in the choice of procedures to be recommended, and if the methods of proved value were presented in a modest manner, avoiding anything in the nature of extravagant claims for the results which could be expected from their application. Immune therapy has suffered much in the past from optimists, and is consequently regarded with mistrust by not a few of those engaged in the practice of medicine in this country. It cannot be said that the author of this book has written in such a manner as to improve this state of affairs. In a preamble of some ten pages the various forms of immune therapy, such as antiserums, immuno-transfusion, and different kinds of vaccines, are clearly described and their limitations indicated. The remainder of the book is divided into two portions. In the first the different serums and vaccines are discussed, and their mode of action and the general results obtained by them examined in detail. The application of these procedures in the various realms of surgical practice is then dealt with in the second part. There is quite a lot of sound advice to be found in these pages, but so much that is questionable has been included as to render the book of little value to anyone whose lack of knowledge would prevent him from reading critically. Another feature which reduces considerably the value of this book is the ignorance which its author displays of work done outside France. To give undue prominence to the work done by fellow-countrymen is but a human failing, understandable even though undesirable in scientific writing, but to push it to the extent of attributing the concentration of antiserums to the pioneer efforts of Besredka and Ramon, and of writing on streptococcal and pneumococcal antiserum without the least mention of all that most valuable work which has originated from America, is not only foolish but inexcusable.

BEDSIDE PREPARATIONS

So many books published to help nurses in their practical work are too long, or are written in such cumbersome English that it is often difficult to know just what the writer really means. In *Practical Preparations*,[4] by Miss N. POWELL, a sister at St. Bartholomew's Hospital, neither of these disadvantages can be found. The terse, short sentences express what is wanted, and no more, with the result that in this small book of 206 pages there is an astonishing amount of information which will be useful not only to nurses in private and hospital practice, but even to doctors. Detailed instructions are given for the preparation of trays such as stimulant, hypodermic, enema, and rectal trays. Methods and things necessary for the collection of specimens for pathological investigation are succinctly set forth, with useful hints for the recognition of gall-stones, tapeworms, etc., in the stools; and the routine procedure to be adopted in preparing patients for *x*-ray examination of the alimentary tract with barium, of the bronchi with lipiodol, of the gall-bladder with sodium tetraiodophenol-phthalein, is clearly and briefly outlined. The omission of special methods of *x*-raying the urinary tract should be remedied in future editions. In the section on urine testing a method of examining for bile is given which is rarely mentioned even in the standard medical textbooks. As this test is not only simple, but also the most sensitive, we may give the author's description of it: "Half-fill a test tube with urine, and shake thoroughly; if bile be present, the froth will be coloured yellow." The nurse, the medical student, and that bewildered being the newly qualified man who has just been appointed house-physician, will turn to many of these pages with feelings of gratitude, particularly to those dealing with local applications. How many final-year medical students, let alone nurses, know how to apply a mustard leaf, antiphlogistine, mustard and linseed poultices, blisters, dry cups, and leeches? "Should it be necessary to remove the leeches, put a little salt on their heads; they will then drop off. They must not be pulled off, or the bleeding will be extremely difficult to arrest." It is these small observations, the outcome of practical experience, which make the book so useful. Methods of reducing temperature by cradling, ice cradling, sponging, by packs, and by baths are given in full detail, as also are the various ways of inducing diaphoresis. Rectal feeding, rectal lavage, and colonic irrigation are also dealt with in this section.

Two sections will appeal especially to general practitioners who wish to have exact knowledge of practical medical methods that may not have been in use in their student days. The first of these is the administration of continuous nasal oxygen, now thought by many to be an essential routine procedure in the treatment of pneumonia. The second includes lists of diets for use in pneumonia, typhoid, and nephritis, with modified Lenhartz and Sippy diets for gastric and duodenal ulcer, and ladder diet and line ration diet for diabetes. Times and amounts are given in detail, with instructions how to prepare special solutions, such as rice water.

NOTES ON BOOKS

The third edition has now appeared of Dr. René Cl ogne's practical guide to analysis of the urine, blood, gastric secretion, and faeces.[5] The subject-matter has been thoroughly revised and brought up to date ; it will assist many general practitioners to understand the scope and nature of modern laboratory tests, and to appreciate their interpretation from the clinical point of view. As a simple laboratory textbook this volume will have its uses, though it makes no pretence of being a complete record of all the investigations which are nowadays necessary. Biochemistry receives more attention than in previous editions.

The War Office in February last notified in Army Orders the issue of an *Army Manual of Chiropody*,[6] of which a copy has been forwarded to us. This small pamphlet contains chapters on the elementary anatomy of the human foot, on the fitting and care of boots, socks, and puttees, and the care of the feet, and on hyperidrosis, corns, the care of the nails, on flat-foot, and other minor deformities, and on chilblains, frostbite, and trench-foot. The appendices contain hints to instructors in chiropody, suggested programme for a course in that subject, rules and regulations for regimental chiropodists, list of contents of a case of chiropody instruments, and of materials required. Presumably this pamphlet is not intended for the rank and file, but for the guidance of the chiropodists who are being trained according to para. 775 of King's Regulations, 1928, by officers of the R.A.M.C. No doubt, also, it will be used by unit officers who have to conduct feet inspections.

The *Abstracts of Dissertations Approved for the Ph.D., M.Sc., and M.Litt. Degrees in the University of Cambridge for the Academical Year 1929–1930*[7] consist of brief synopses of studies in various subjects, including agriculture, botany, geology, zoology, biochemistry, physiology, experimental psychology, history, literature, and economics. Among the theses of interest to the medical profession is that " On the bicarbonate and chloride ratios, carbon dioxide dissociation curves, and cell volumes of oxygenated and reduced ox bloods, normal and abnormal, and a comparative study of these bloods with the bloods of the sheep, pig, horse, man at rest, and man at work," by W. O. Morgan ; " Periods of arrested progress in the acquisition of skill," by M. D. Smith ; and " Studies in bacterial metabolism," by R. P. Cook.

" Aglait Illisimatiksat " is the Eskimo equivalent of " Book of Knowledge."[8] Its author, Mr. George Binney, is of the Hudson's Bay Company, London. He tells us in an interesting preface that although many of the Eskimos of Labrador have learned to read and write, there has been until now only one book printed in their language—namely, the Bible, with a liturgy and a few religious tracts. With the increase of sophistication, there is serious danger of demoralization and deterioration of these amiable and hardy people, and the Hudson's Bay Company has therefore had this elementary handbook of hygiene prepared and translated into the Inuit language. It is intended to be sold and not given away, because, as the author says, the Eskimo, like the white man, values most the things he pays for. The English and Eskimo texts are printed on opposite pages, and at the end of the book are maps of Canada, Labrador, Greenland, etc., drawn in the style of the sixteenth century, and so presumably more intelligible to the primitive reader than modern maps. Whether that is so we may doubt, but the *maps are certainly picturesque*. The English version is in simple language, but it might have been even simpler. Such words as retain, produce, obscured, prepared, summit, obtain, etc., might easily be changed for more homely synonyms. The text has been rendered into the Labrador dialect by the Rev. W. W. Perrett, for many years superintendent of the Moravian Mission in Labrador.

Hutton, M.D. London: Hudson's Bay Company, 68, Bishopsgate, E.C.2. 1931. (Pp 237 ; illustrated. A limited number of copies are available for the public, 8s. net, post free, on application to the Hudson's Bay Company.)

PREPARATIONS AND APPLIANCES

Naso-pharyngoscope for Radium Application

Mr. John E. G. McGibbon (honorary assistant laryngologist and aurist, Royal Southern Hospital, Liverpool) writes.

The accompanying illustration shows a modified Yankauer's naso-pharyngoscope for the application of radium needles or

radon seeds to malignant growths in the naso-pharynx under direct vision.

The naso-pharyngoscope is distally lighted, and affords a comprehensive and well-illuminated view of the vault, posterior wall, and lateral walls of the naso-pharynx. The lateral wall of the pharyngoscope is slotted (on the opposite side to that drawn in the figure for right-handed operators),

as it has been found that seed-introducers or needle-forceps can be introduced more easily alongside the speculum, and their extremities brought into the field of vision through the slot rather than directly through the lumen of the instrument. The modified naso-pharyngoscope can be used also for simple examination of the post-nasal space, or to obtain specimens of tissue for biopsy.

The radiograph shows fourteen radon seeds which were implanted into an extensive naso-pharyngeal neoplasm through the pharyngoscope under direct vision.

The instrument was made by Messrs. Mayer and Phelps of 59-61, New Cavendish Street, London, W.1.

British Medical Journal

PROBLEMS OF ANAESTHESIA

The blessings of anaesthesia are so evident to patients and the profession alike that to help in perfecting the art and the science of that special branch of medicine is clearly to confer a benefit upon humanity at large. That many attempts to increase the safety and the usefulness of anaesthetics and to minimize their drawbacks have been made, especially during and since the war, is common knowledge ; but the very success of some of these attempts has brought about a dilemma as between specialist and general practitioner similar to that which has confronted the medical profession in other branches of specialized study. Briefly, as Dr. R. J. Clausen has indicated in the very careful and broad-minded review of progress in anaesthesia which he read at the Annual Meeting of the British Medical Association in July, there are methods of simplicity and methods of complexity in the administration of anaesthetics.

Students and junior practitioners can learn the simple methods within the limitations of the time they are able to spare ; and, provided always that they are impressed by their teachers and their textbooks with certain well-established fundamental principles. they can make themselves efficient administrators, with a high degree of safety to their patients for the routine ordinary case. There are very many general practitioners up and down the country at large of whom it can be said that they fulfil this description, as any surgeon will readily admit ; and that the proportion of them is very much higher than it was a generation ago is equally indisputable. This is a state of affairs for which the credit is due to the medical schools. The schools in their turn have to thank the specialists in anaesthesia who instruct their students ; and if both schools and teachers owe a debt to one individual more than to any other for insisting on the vital necessity of studying first principles, that individual is the late Sir Frederic Hewitt. Granting the fact of this all-round levelling up, at the same time it has to be admitted that there are still practitioners using and ready to defend methods which every specialist is convinced are dangerous.

On the other hand, there are methods of complexity, mostly of recent introduction, which appear to offer great advantages in the management of difficult and exceptional cases. There is, of course, no hard-and-fast line possible between the simple and the complex ; what is complex to-day may appear simple to-morrow ; what is complex to some practitioners may be simple to others. Many of these methods are at present almost exclusively in the hands of specialists, and are likely to remain so for a considerable time to come. Granted that some of them offer really great advantages to the patient in certain cases, the problem that Dr. Clausen has in mind is how they can be secured for him when a specialist is not available. To this problem there is virtually no solution except by improvement in the training given to students and residents in the hospitals of the country. But an improvement in the standard of training means of necessity an increased period of time for study, and even more for opportunities of practical work, which the already heavily loaded curriculum will not allow. Since all our students cannot be educated up to specialist standard in every branch of medicine, we shall have to remain content with doing the next best thing—that is, training them very thoroughly in first principles and simple methods, offering concurrently an inducement to much larger numbers of them to qualify as specialists. That inducement must include improved remuneration, among other things ; for it is notorious that even in London only a handful of those who take up anaesthetics as a specialty can make a living without doing general practice of some kind in addition.

Dr. Clausen pleads, also—and he is not the first to do so—for a more sympathetic comprehension by the surgeon of the aims and problems of the anaesthetist. Here, too, there is a very different outlook to-day from that of a generation ago ; it is becoming exceptional for the surgeon to treat the anaesthetist as an interloper whose sole function is to produce a deeply relaxed musculature regardless of everything else, instead of as one of a team of workers co-operating to promote the welfare of their common patient. Nevertheless, even quite recently surgeons have been known to object to nitrous oxide and oxygen on the ground that the operation field bleeds more readily, and to suggest the use of chloroform, oblivious of the consideration that vessels do not bleed unless the surgeon cuts them, and that, if he does cut them, it is better for them to be seen and tied (which is likely to happen when the blood pressure is well maintained, as is the case with gas and oxygen) than not to be seen, not to be tied, and to bleed the next day (which has been known to happen owing to the temporary fall of blood pressure under chloroform). Even more vital is full co-operation and mutual comprehension between surgeon and anaesthetist when the various combinations of local, regional, or spinal anaesthesia, with or without pre-medication and basal anaesthesia, are being employed. Here the factor of time is of importance ; in hospital work especially there is too great a tendency to rush and hurry, Dr. Clausen feels, and too little respect in consequence for the patient's point of view of all these matters. This brings us back once more to the economic factor ; for time is money. Without a certain amount of drive in the operating theatre, programmes would never be got through at all ; but all the same there is much force in Dr. Clausen's contention, and one at least of the incidents which he narrates in support of it is clearly indefensible, and, we may hope, quite exceptional.

"HEALTH AT THE GATEWAY"

The problems which engaged the attention of the pioneers of the sanitary movement in England, though they presented themselves in a serious form in congested inland industrial centres, assumed a still more formidable guise in rapidly expanding seaport towns, whose native shortcomings were subject to aggravation by recurrent outbreaks of alien infections introduced in the course of oversea trade. Among such communities the city and port of Liverpool must be held to occupy a conspicuous place, alike for the great and even unique character of the stresses it experienced, and for the very notable success with which these difficulties were overcome. The various steps in the path of progress by which the "most unwholesome of seaports" rose to a level of sanitary efficiency which is acclaimed by all have been set forth by Professor E. W. Hope in a recent work[1] under a happy title, in which he narrates the course of events, portrays the changing conditions of the city, and reviews the remedial measures adopted, many of which he inspired and administered. The sanitary development of the port is traced from the early days of strict quarantine at Sloyne, where suspected ships were detained for long periods, guarded day and night, down to the formation of the Port Sanitary Authority, whose modern methods are more efficacious and more considerate of commercial interests.

The early history of the town itself reveals interesting conditions. It appears that in 1801 2,306 persons in Liverpool were living in cellars. A little later the amazing volumes of smoke which poured incessantly from the works were regarded as "in some respects salutary for the sulphur which they contained." The water supply, however, was less copious, being issued from carts to the inhabitants at a halfpenny a bucket. When the local Sanitary Act of 1846 came into operation the potato famine in Ireland was driving crowds of destitute immigrants into Liverpool. By June 30th, 1847, some 300,000 had landed, and 60,000 and over settled in the town, forcing their way into cellars which had been closed as uninhabitable. Fever broke out and continued to spread. By the end of the year there had been 60,000 cases in the town, together with 40,000 of dysentery. In one district 1 person in 7 died. Over the city as a whole 2 in 7 were stricken. Next, in 1848, cholera came from Dumfries, and in 1849 from Glasgow and Dublin, and the resulting deaths were 6,394. From those repeated shocks, however, the sanitary provisions contained in the Act of 1846, though delayed for the time, gained added force, and, conferring as they did upon the city powers to facilitate scavenging, cleansing, and water supply, and to prevent overcrowding, heralded the approach of a new sanitary era. Another time of pressure was experienced during the cotton famine of the American Civil War, and in 1865 and 1866 the zymotic diseases were still swelling the mortality lists. But a recrudescence of typhus in 1882 and 1883 spurred the council to establish a fever hospital, and the sanitary staff was largely increased in order to deal with the position, though the compulsory notification of infectious disease, possible under the then adoptive Infectious Disease Notification Act, was still opposed by both lay and medical opinion.

District nursing or its equivalent originated in Liverpool in 1859 by voluntary effort, and, owing to the difficulty of finding suitable nurses, a training school for nurses was instituted in 1863, the architect for the building being advised on his plans by Florence Nightingale. Child welfare work began in 1874 in a voluntarily supported day nursery, and in 1897 two women were appointed to the sanitary staff to act as health visitors. The need for the training of health visitors was met by the establishment of the University School of Hygiene. In 1901 the corporation made grants to voluntary agencies supplying milk for infants, and from this beginning the work rapidly expanded till crowned in 1916 by the establishment of the Carnegie Welfare Centre. In connexion with these matters Professor Hope draws attention to the important part played by the University of Liverpool and other universities in the advancement of public health reform. The provision of water for Liverpool was first empowered in 1786 by a local Act of Parliament, and subsequent Acts incorporated two private water companies to meet the needs of the town. The Rivington scheme was authorized in 1848. In 1873 and later the council weighed the rival claims of Bala Lake, Derwentwater, Windermere, Haweswater, and the River Vyrnwy as sources of a high-grade water supply. The choice finally fell upon Vyrnwy, whose great impounding reservoir now furnishes the city with a pure water from sixty-eight miles away at 1½d. a ton. The activities of the corporation in school hygiene, housing, food control, and other undertakings are also fully and clearly reviewed.

Professor Hope records that Liverpool was first in this country to support a medical officer of health, sanitary officers, a city bacteriologist, and women health officers, and was also the pioneer in district nursing, child welfare work, and the training of the blind. The helpful co-ordination of voluntary effort with official schemes emerges often in the story. The period covered is far longer than that of Professor Hope's own tenure of the post of medical officer of the city, and he refrains from focusing attention on matters in which he was intimately concerned or was the prime mover, but his distinguished service is too well known for modesty to disguise. His wide experience and enlightened outlook are set forth in a vigorous and attractive historical study, and what he has written in *Health at the Gateway* will not only stand as a valuable record of good work done, but will serve also as a guide and stimulus to his younger contemporaries in the public health service in the discharge of their increasingly onerous duties.

[1] *Health at the Gateway*. By E. W. Hope, O.B.E., M.D., D.Sc. London: Cambridge University Press. 1931. (15s. net.)

RADIOLOGY AND THE RADIOLOGIST

A generation has passed since the introduction of *x* rays. In the early days the radiological specialist was essentially a technician, and in many instances was not even qualified in medicine. Where the exposure was of long duration (twenty minutes was not too much to give in order to obtain a skiagram of the skull), and the risk of mechanical breakdown of apparatus always imminent, it was necessary to have in charge of the machine someone conversant with its peculiarities who could, without loss of time, make the necessary adjustments and minor repairs. The finished skiagram could be examined at leisure by a man skilled in anatomy, who could then offer the correct interpretation. Formerly, the fixed skeleton was the only part that could be adequately examined. In more recent times, with improved technique, the soft and mobile tissues have also been explored. Nowadays, too, the improvements in design and construction of apparatus allow a greatly increased penetration of rays with a minimum of bother. The comparatively simple control table sets into action a most elaborate switchboard, hidden from view behind a screen in the corner, and requiring a team of skilled workers to unravel and adjust its intricacies; but the actual management of the apparatus appears to require little more than careful attention to a few simple rules of sighting and exposure. Nevertheless, the differences between the results obtained by various workers are so great that we are tempted to look a little more closely into the psychological basis of the *flair* which some possess and others do not. What are the attributes of those who will most successfully tame and employ this monster, at once so docile and so dangerous, devised and constructed by an army of Frankensteins? First, however, we must inquire as to the line of *x*-ray development itself. Will the perfection of the machine, making it fool-proof, allow of its manipulation by every practitioner, or will a specialist branch still be required? Is the *x*-ray apparatus in future to be used, for example, as the electrocardiographic apparatus is used, or as the stethoscope is used? It must be employed more commonly than the former, since the *x* ray offers an unrivalled method of envisaging the skeleton, and of estimating the condition of hollow viscera and soft tissues when these are thrown into relief by barium or bismuth or organically combined iodine. In some of the most up-to-date clinics in Germany radiography has displaced even the stethoscope in the management of phthisis. The cases are almost entirely controlled by laboratory methods, the diagnosis being made by the *x* ray and the prognosis by the sedimentation rate of the red blood corpuscles. Though this is going further than could be acceptable to the clinical traditions of British medicine, radiographic aid is becoming almost a daily need in practice. Efficient and easily worked outfits are available, and knowledge is spreading. A number of *x*-ray atlases and reference books have been published during the past year or two and reviewed in our columns, containing beautifully reproduced illustrations of the *x*-ray appearances of normal and abnormal conditions of bones, joints, and internal organs. The object in publishing these expensive works appears to be to provide a reference library for practising radiologists, whose subject grows so big that specialization is taking place even within its confines. Besides these library editions, however, there are many smaller books which give in not too great detail the methods and the more common results of applying *x*-ray methods. From these the practitioner may learn what will help him in the majority of his cases. In a considerable number, however, his results may be incomplete or negative, and yet a doubt remains about the presence of a lesion. Here an expert must be called in. It should be noted that repetition of *x*-ray examination for reviewing the case is not without considerable risk, owing to the irritative effect of these rays on the skin and superficial tissues of the patient. The future of radiology as a specialty would indeed be hazardous if the consulting radiologist were thus restricted in his opportunities and hampered in his investigations owing to the previous irradiation of the patient's skin. There seems, however, no reason to believe that such may be the trend of this branch of medicine. The radiological expert with an established technique may feel that in methods of diagnosis little remains to be improved; but research in methods of treatment is only beginning. The control by *x* ray and radium of malignant disease—lymphadenoma and leukaemia, for example—is still the subject of much work and discussion. Different radiologists advocate different methods. Careful observation will be required to establish the most efficacious procedures. A start has been made, but in this field of research a great deal remains to be done. Research, however, is for the few. Though all may contribute to the advance of knowledge in some degree by accurate observation and recording of facts, it is rarely that there arises the genius of a synthetic mind to correlate these facts into an ordered body of truth. The radiologist's job is to study form; the best produce a picture of the actual lesion for all to see. This striving after the complete representation reveals the artist. But there is also interpretation. The radiologist is working with shadows on a two-dimensional plane of solid objects in the world around him, and, like other artists, he must suggest the condition of familiar objects—in this case objects of anatomy and pathology.

A MONOGRAPH ON HEART DISEASE

Excessive concentration upon acquired structural cardiac defects was replaced towards the end of the nineteenth century by an unduly exclusive attention to the functional capacity of the heart. The pendulum now swings again, and Dr. Paul D. White[1] laments the modern neglect of physical signs in so far as these conduce to more exact knowledge of morbid anatomy. He therefore bases the present-day conception of cardiology on the "tripod of cardiac diagnosis"—etiological diagnosis, structural change, and functional condition. Physicians, he considers, should direct their attention rather to the first and second than to the last of these elements in diagnosis. In discussing the incidence and causation of heart disease, he remarks that no other single disease group causes death so frequently. This must be due in part to the diminishing deaths from such diseases as tubercle and pneumonia, with a resulting prolongation of life to the age at which degenerative changes set in.

[1] *Heart Disease*. By Paul Dudley White, M.D. The Macmillan Medical Monographs. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1931. (42s. net.)

Several useful tables are given in Dr. White's monograph: one compiled by Abbott contains a classification of congenital cardio-vascular defects, together with their relative frequency, compatibility with life, associated anomalies, and mode of death. Another tabulates statistics from the United States and Europe as to the percentage contribution of the various etiological factors in death from heart disease. Opportunity should be taken in a future edition to omit the series studied by Parkinson and Clark-Kennedy, as this concerns failure with normal rhythm only. Dr. White rightly claims that the determination of etiology is sometimes more important than a structural diagnosis, and he deals very adequately with certain factors whose claim to cause heart disease has in the past been contested. Scarlet fever is placed in the category of rare causes; obesity, strenuous exertion, and tobacco are exonerated on the count of disease causation, but held to be often productive of symptoms and contributory to distress where disease from another cause coexists. On the other hand, insufficient consideration is given to the heart in pneumonia and other acute infections. No description of the circulatory embarrassments in these diseases is given; nor can it justifiably be held that pneumonia does not cause heart disease when it has been demonstrated by Stone that myocarditis is found at necropsy in more than 10 per cent. of patients. In the opening chapters on cardio-vascular examination, very careful consideration is given to history taking and to clinical methods. The importance of investigating functions and organs frequently involved in heart disease is stressed, and a chapter is devoted to this aspect of clinical work. In the realm of clinical cardiological investigation the radiology of the heart is assuming an ever-increasing importance. In fact, the *x* ray, as well as the electrocardiograph, must be regarded as indispensable in the examination of a patient seriously suspected of cardio-vascular disease. Many helpful orthodiagrams accompany Dr. White's very lucid exposition of the technique of screening and orthodiagraphy, and, in addition, there are some reproductions of the excellent drawings of Koch and Wieck. These represent the post-mortem tele-radiogram appearances of hearts in which metal strips and bands have been employed to outline the various chambers, valvular orifices, and vessels. The author's account of radiological methods must be invaluable to those who desire to study the heart possibly or certainly diseased. While the detailed discussion of symptomatology is a valuable feature of this monograph, it appears that in order to avoid much reiteration differential diagnosis has been scantily treated. For example, this aspect of angina pectoris is too briefly mentioned. Concerning the relationship between true angina of effort and neuro-circulatory asthenia, Dr. White remarks that the latter condition "may complicate angina pectoris and even confuse the diagnosis." No one will deny that the difficulty of differentiating angina and the painful forms of neuro-circulatory asthenia is occasionally great, and may be insurmountable. But probably most clinicians would also agree to Gallavardin's assertion that they never truly coexist: "Sans pouvoir catégoriquement nier sa possibilité, je puis bien dire que je n'ai pas observé d'angor d'effort absolument net dans l'angine de poitrine névrosique." Another important clinical point that might have received mention is that variety of angina of effort supervening as a sequel to dyspnoea, usually in hyperpietics, and carrying no menace of death in the attack. But no description or criticism of Dr. White's work can convey the wealth of information that it contains or the stimulating philosophic and scientific spirit in which it has been compiled. Moreover, he has sifted an immense mass of important contributions to the subject in producing a treatise that must have a strong influence upon cardiological thought of to-day.

LONDON WATER

In the introduction to his report for 1930 on the water supply of London,[1] Sir Alexander Houston recalls a number of his past contributions to the study of the characters of potable waters and the methods by which potability is maintained. He refers to his important determination in 1908 of the viability of *B. typhosus* in water, and also to his search of 1928 for the presence of this organism in the raw water of the river. Included in his survey are the uses of storage, rapid filtration, and the excess lime method. The new material of the report sets forth, in the first place, the consistently good results achieved during the year by chlorination, *B. coli* being absent from 100 c.cm. samples of water in percentages ranging from 94.4 for West Middlesex to 98.0 for Kempton Park and Southwark with Vauxhall. In 1930 the Barn Elms experiments in double filtration were on the whole satisfactory; they will not be separately described in future reports, as similar work on a larger scale is now carried out at Walton and Kempton Park. An investigation was made with the view of ascertaining the frequency of *B. typhosus* in sewage, the medium employed being Wilson and Blair's glucose-bismuth-sulphite-iron. In thirty-four twenty-four-hour average samples of London sewage from the Barking outfall, four only contained one typhoid colony each in 0.1 c.cm. of sewage, the remaining thirty all being negative. The attenuation of such a suspension is well conveyed to the mind by the control examination of thirty-four equivalent samples of the sewage artificially inoculated with the bacillus, from all but one of which colonies were recovered in numbers ranging from 1 to 65, with an average of 10.9. Nine further samples were tested for *B. paratyphosus* B, with negative results. The author adds, however, that in the course of another investigation, not detailed in this report, he found no fewer than 73 paratyphoid bacilli per c.cm. in the sewage effluent of a town (unnamed) during a paratyphoid outbreak. In view of the abundance of streptococci in human faeces, their non-multiplication in pure water, and their feeble viability in water generally, he is of the opinion that, if they could be differentiated from their more robust congeners, their presence in drinking water would furnish a valuable indication of recent and specially dangerous pollution. He describes a method according to which the growth of *B. coli* is repressed by partial drying, while the streptococci, which are comparatively resistant to drying, survive. In the miscellaneous section, under the heading "There is

[1] Metropolitan Water Board. Twenty-fifth Annual Report on the Results of the Chemical and Bacteriological Examination of the London Waters for the Twelve Months ended December 31st, 1930. By Sir Alexander Houston. London: P. S. King and Son, Ltd. 1931. (21s.)

othing new under the sun," a curiously interesting tter is reproduced, dated one hundred years ago. It from Michael Faraday to the then engineer of the 'est Middlesex Waterworks Company, reporting on a green substance " sent to him for examination. He ays that he believes the substance to be a conferva, but omplains that the engineer had supplied him with no etails as to the source and circumstances of the growth. Being without details he can express no opinion as to ow to stop its formation! Such complaints by experts, s the heading suggests, are not unknown at the present ime. The report concludes with a description of the iew waterworks at Kempton Park, where double filtra- ion has been introduced with satisfactory results, the amount of water filtered being two and a quarter imes the previous normal daily output of the station. The plant is illustrated by a drawing and photographs, and the route to Kempton and back is traced with a wealth of anecdote and quotation.

CEREBRO-SPINAL FEVER

A memorandum[1] has been prepared in the Medical Department of the Ministry of Health summarizing the epidemiology and characteristics of cerebro-spinal fever, and describing the means of control and specific treatment, with special reference to a scheme for collecting the results of serum treatment. It amplifies and replaces the previous memorandum on this disease which the Local Government Board issued in 1918. Sir George Newman in a prefatory note remarks that the fact that during the past year there has been a definite increase in the prevalence of cerebro-spinal fever in different parts of England and Wales affords an additional reason for the present summary. As regards the assessment of the value of the available serums, and of the different dosages and methods of administration employed, he expresses the hope that medical officers of health, hospital medical officers, and general practitioners will report to the Department on a uniform plan the results that have been obtained with serotherapy, so that some general conclusions may be reached. The clinical details required include the dates of onset, notification, and removal to hospital ; the dates of performing lumbar punctures, and the amounts of fluid so removed ; the dates of administering anti-meningococcal serums and the doses injected (intrathecally, intravenously, or intramuscularly) ; the source of the serum ; and its apparent effect. In the body of the memorandum is a table of the incidence and mortality of this disease each year since 1912 ; the increase in 1929, 1930, and the first quarter of 1931 is noteworthy, the last figure suggesting the possibility of a higher incidence this year than in any year since 1919. Stress is laid on the tendency of the disease to affect children under the age of 5, and the close association of susceptible persons with carrier cases in schools, mines, and naval depots. The infection is of the " droplet " kind, and the chief danger lurks in unrecognized carriers ; there is a relatively low case-to-case infectivity. The virulence of the specific micro-organism recovered from carriers cannot, unfortunately, be estimated, as in the case of diphtheria, where virulence tests have proved so valuable. As regards treatment, the important points stressed are: good nursing ; early and repeated lumbar puncture to relieve pressure, and to promote drainage of the cerebro-spinal system ; the administration of anti-meningococcal serum at the first lumbar puncture, and thereafter at intervals of twenty-four hours ; and the injection of adrenaline (to combat shock in fulminating cases), morphine, and heroin. The intrathecal route is preferred for serum injections, but in some cases intravenous and intramuscular administration has proved beneficial. It is admitted that serum therapy has been ineffective in some recent cases, in striking contrast to the success thus obtained during the war. This may be because most of the cerebro-spinal fever prevalent in the war period was associated with one or two identifiable serological types of meningococcus, whereas other types have since come into activity. This emphasizes the main purport of the memorandum, which is to secure the collecting of information about the effectiveness of the different varieties of serum now in use, and the methods of their administration. Meningococcal vaccine may be employed in the long convalescence stage, but there are as yet no satisfactory data available concerning its prophylactic value. In the case of persons travelling from an uninfected area into a community where the disease is prevalent, it is suggested that doses of 500 and 1,000 million cocci may be injected, such cocci consisting of the types predominating in the affected community. While it is not advised that contacts and carriers should be isolated, special efforts should be made to free them from the cocci by a routine of fresh air and exercise ; as an adjunct, spraying the nasopharynx with a 1.5 to 2 per cent. solution of zinc sulphate may be tried.

CONVALESCENT CARE

The Winifred Masterson Burke Relief Foundation was founded and endowed for " the relief of worthy men and women who, notwithstanding their willingness to support themselves, have become wholly or partly unable to do so by reason of sickness and misfortune, or have been discharged from hospitals before they have regained sufficient strength to resume their employment." Its main institution at White Plains, Westchester County, New York State, was opened in April, 1915. It occupies a site of sixty acres, and can accommodate 300 patients. It was used for convalescent purposes by the United States Navy from January, 1918, to April, 1919 ; and in this institution and some small branch homes there have now been treated some 90,000 patients. The ninth report of the Foundation, covering the period May, 1929, to April, 1931, has been issued, and provides a record, with no fewer than fifty admirable photographs, of activities and experiences which may well influence similar movements both in this country and in America. The report shows that the work of the Foundation has been devoted to the latter of its two objects—namely, relief, help, and care during, and immediately subsequent to, convalescence, and the essential difference between this function and that of supplying the needs of chronic cases is emphasized. The distinction must be peculiarly difficult in two classes of case to which some particular attention has been given, " selected cardiacs and mild

psychoneurotics." The report states that "good convalescent treatment is found to be made up of about 50 per cent. inspirational human management, 40 per cent. housekeeping, and only 10 per cent. of nursing. . . . Convalescent care becomes, in best practice, predominantly psychotherapy." This last term, however, clearly has a wide meaning for the authors of the report, for it includes both "occupational therapy" and "recreational therapy." The way in which these are applied has undergone some modification during the past two years in the light of previous experience, and their advantage and great importance during the later stages of convalescence are pointed out. Convalescence may be a critical period in the life of a sick man or woman. Whether recovery or chronicity is to result may depend upon the way in which this period is handled. Experience, such as that recorded in this report, is therefore of considerable value, and opportunities such as those provided by the Winifred Masterson Burke Relief Foundation may well be brought to the notice of philanthropists elsewhere.

BRITISH ASSOCIATION CENTENARY

As previously announced in our columns, the British Association for the Advancement of Science will hold its centenary meeting in London, under the presidency of the Right Hon. J. C. Smuts, from September 23rd to 30th. Concurrently, the Faraday centenary exhibition will be held in the Albert Hall, where General Smuts will be installed on the afternoon of the first day, and will there receive the delegates of societies, institutions, universities, colleges, and cities in which the Association has previously held its meetings. The presidential address will be delivered on the evening of the same day in the Central Hall, Westminster, the subject being, "The scientific world-picture of to-day." Subsequent evening lectures will be given by Sir Arthur Keith, on the construction of man's family tree; by Dr. S. Kemp, on oceanography in the Antarctic; and by Sir Oliver Lodge, on a retrospect of wireless communication. A large number of receptions have been arranged for the delegates, the hosts including the National Physical Laboratory, Bedford College for Women, the Royal Society, the Government in the Imperial Institute, the Wellcome Historical Museum, the University of London, the Forum Women's Club, and the Lord Mayor and Corporation of the City. The greater part of each day will be occupied by discussions. Among the topics of special interest to medical practitioners is a lecture on experiment and observation in the study of child psychology, which will be given on September 24th by Professor C. W. Valentine. On the following day Sir Frederick Gowland Hopkins, President of the Royal Society, will open a discussion on the chemistry of the vitamins and related substances; and on the same day lectures will be given on the social aspects of mental deficiency, by Dr. E. O. Lewis; on the role of genetics in the future of preventive medicine, by Dr. C. P. Blacker; on some psychological experiments on different types of mental defectives, by Drs. R. G. Gordon and Norman; and on the classification of the mental defective and the relative frequency of different types of such deficiency, by Dr. F. C. Shrubsall. On Saturday, September 26th, a discussion will be held on popular problems, to which Professors J. S. Huxley, E. W. MacBride, F. A. E. Crew, and Mr. J. B. S. Haldane will contribute. Dr. H. H. Dale will deliver his presidential address to the Section of Physiology on Monday morning, September 28th, when he will introduce a discussion on the biological nature of filterable viruses. In the Section of Education on the same day there will be a discussion on school clinics and child guidance, which will deal with the problems presented by the maladjusted child, and the value of psychological examination as an aid to vocational adaptation. Air Vice-Marshal Sir David Munro will preside over a discussion on September 29th, on the physiology and psychology of work; and on the same morning, in the Section of Physiology, problems of resuscitation after asphyxiation, anaesthesia, electrocution, and drowning will be considered by Professors Yandell Henderson and J. S. Haldane, Sir Francis Shipway, and Sir Bernard Spilsbury, among others. The Huxley Memorial Lecture of the Royal Anthropological Institute will be delivered the same evening by Dr. J. Thilenius, on some biological view-points in ethnology. Among the excursions arranged are visits to York, where the Association was founded; to Darwin's home at Down House; Liverpool Cathedral; Kew Observatory; Whipsnade Park; the Royal Naval College; the Royal Observatory; the Heritage craft schools and institutions at Chailey and Bishopstone; Colchester; and Romney Marsh. Special attention will be directed to educational centres, and a booklet will be provided dealing in detail with the University of London, the education department of the London County Council, and various unofficial teaching institutions likely to interest members of the Section of Educational Science.

THE EDUCATIONAL NUMBER, 1931

Our next issue, dated September 5th, will be the annual Educational Number of the *British Medical Journal*. Its contents, as in previous years, will include a full account of the requirements of the General Medical Council and of the universities and other licensing bodies in Great Britain and Ireland, as well as information about the opportunities offered by the various medical schools and other teaching institutions, and the fees charged by each. The details given have been revised and brought up to date by the authorities concerned. These sections, the object of which is to furnish a handy guide to intending students of medicine, are supplemented by articles intended for newly qualified practitioners on such matters as post-graduation study in Great Britain, the public health services, tropical medicine, psychological medicine, and the various special diplomas. In the sections dealing with the public services will be found a concise account of the present terms and conditions of service in the R.N.M.S., the R.A.M.C., the I.M.S., and the R.A.F.M.S., which the Representative Body of the British Medical Association has decided are satisfactory and such as can be commended to the notice of the younger members of our profession. The opening article for this year's Educational Number, entitled "The preliminary sciences in medicine," has been written by Dr. R. J. S. McDowall, professor of physiology, and formerly dean of the Faculty of Medicine, King's College, University of London.

POST-GRADUATE MEDICAL WORK IN HUNGARY

e have received from Professor Emile de Grósz, esident of the Hungarian Medical Post Graduate Comittee,* the following account of courses available to edical graduates in Hungary It will be recollected at an article on post graduate studies in Germany was ıblished in our issue of August 1st (p 218)

With the rapid advance of medical science even the ost highly efficient doctors constantly need to supplement their knowledge To day patients are cured who few short years ago were pronounced incurable Confidence in the success and safety of operations is daily ecoming greater, and the knowledge of fatal diseases ıore complete These facts render it imperative that ıedical practitioners should be in a position to perfect heir knowledge from time to time In all civilized states opportunities exist to this end, but the means provided are different In some countries the work is undertaken voluntarily by institutions and social organizaıons, in others it is placed in the hands of the medical aculties of the universities, while in two countries—Germany and Hungary—central committees exist for this purpose

On the occasion of the sixteenth International Medical Congress, held in Budapest in 1909, the Comite International pour l'Enseignement Médical Complémentaire was founded, and its first session, under the presidency of Sir Donald MacAlister, was held at the seventeenth International Medical Congress which met in London in 1913 The discussions that took place at this meeting were published in book form in 1918 The time is now most favourable for the delegates of individual States to discuss the various methods of instituting medical postgraduate work, since the congresses held during the past few years all indicate that the representatives of science, without violating national sentiment, could successfully unite in common action

Historical Note

In Hungary from 1883 to 1904 there were summer courses devoted to the subject of post graduate training These were always arranged during the holiday months by the professors and lecturers of the Budapest University, and also, later on, by the Kolozsvar University, and were attended annually by about a hundred doctors Up to 1918 an aggregate of over a thousand doctors took part in these extension courses No actual problems, however, could be satisfactorily solved at these meetings

Organization of Central Committee

In view of the rapid development of medical science, every doctor should have an opportunity of furthering his professional knowledge at least once in every five or ten years Prompted by this consideration, I submitted in 1908 a proposition to the Minister of Public Instruction for the creation of a central committee, and the founding of a periodical to serve the interests of the desired object The conference was called in December, 1908, by Count Apponyi, who accepted the draft of the statutes which I prepared, while his successor in office, Count John Zichy, brought the central committee into being

The duties of the central committee are to arrange post-graduate courses for civil and military doctors, to found and recommend internal and external institutions, and to organize local committees in the larger provincial towns, further, to found a periodical for the publication of lectures and other scientific work

The cost of the post graduation scheme is borne by the Minister, partly from a charge upon the State budget, and partly from the interest provided by an endowment fund In order to enable doctors of small means to participate in the courses, the central committee endeavours to enlist the aid of various authorities, sick relief bureaux, and the chief commercial enterprises with their medical departments

Arrangement of Courses

Courses are arranged in the following order

1 Post graduate courses of fourteen days with numerous lectures upon the various branches of medical science

2 Special courses of four weeks duration for not more than six doctors who desire a deeper knowledge of the particular branches of their profession These courses are held at clinics, well equipped hospitals, and institutes, in such a manner as to afford students an opportunity of taking part in the day's work Each participant in these courses receives material aid from the committee, either in the form of money or by accommodation in institutes

3 For the benefit of medical officers, fourteen day courses on hygieno bacteriology are arranged

4 For lectures on subjects pertaining to certain minor specialities there are a suitable number of eight day courses

5 With the co operation of the local committees of seven of the larger provincial towns, post graduate courses, lasting from six to eight weeks, are so planned that the lectures occupy one or two days per week only This arrangement has proved very satisfactory, as it enables country doctors to take part in the courses without neglecting their work at home

Subjects of Instruction

During the past twenty years the committee has effected the further training of upwards of four thousand doctors Year by year new subjects have been introduced, of which those relating to infants and child protection have been particularly popular Occupational diseases and accidents have formed the subject of special courses Courses of instruction in tuberculosis have been held at the Queen Elisabeth Sanatorium, while at other public places in Budapest similar courses have been given, dealing with physical therapy, venereal diseases, trachoma, and dentistry During the past few years social hygiene has also received attention

Finance

The periodical *Orvoskepzes* ("The Post graduate") comprises sixty to eighty sheets annually, and during the twenty years of its existence has published more than a thousand essays by competent writers Owing to the paucity of means at the committee's disposal, it has been able to fulfil its mission only by generously giving its services gratis, and by the fact that the lecturers have been content with an exceedingly small remuneration The editors and contributors of *Orvoskepzes* have worked gratuitously, all available funds being devoted as stipends to the provincial doctors for the purpose of defraying their expenses, and to enable them, by suspending their professional appointments, to participate in the courses All the courses are free of charge with the exception of the nominal payment of an entrance fee of 5 pengo (1s) To certain doctors the committee gives grants of 100 to 200 pengö

Government Co operation

The Minister of Public Affairs has founded a doctors' home in Budapest, where those attending the courses may obtain board and lodging either gratis or at a moderate charge The Social Insurance Institution affords special facilities to its doctors to enable them to take part in the continuation courses To promote the development of obstetrics in accordance with the steps taken by the Ministerial Commissioner for Obstetrical Affairs, eleven free places have been allocated to doctors at the women's clinics and midwifery schools

* The address of the Central Office of this Committee is Budapest, VIII, Mara utca 39

Some Figures

Last year 411 doctors took part in post-graduate courses, which were held not only in the faculties of the provincial universities, but also in the hospitals of the provincial towns. It is especially for the provincial doctors that the courses are designed. In Hungary there are 8,000 medical practitioners, of whom more than 4,000 are located in Budapest, and a considerable number in the larger towns.

Conclusion

The problem of medical post-graduation permits of various solutions. It would be well, therefore, to take up the discussion of methods and results and to continue the exchange that was begun in London in 1913. To this end it would seem desirable to have a preliminary collection of data, which could best be done through the Government by means of questionaries. When the data thus obtained have been printed, a conference of delegates will have to continue the work begun in Budapest and in London.

Nova et Vetera

THE THACKERAYS

At the first anniversary meeting of the Provincial Medical and Surgical Association, held at Bristol in 1833, the Council's report contained the following passage:

"They cannot help calling the attention of the members to the liberal proposition of Dr. Thackeray of Chester, who transmitted five pounds to the secretaries, and in a letter to them which accompanied this donation he states: 'If nineteen other individuals would subscribe twenty pounds each and place the money in some public security, I would add fifteen more to the sum I have transmitted. The interest of the £400 might be given annually for the best essay on some medical or surgical subject.'"

Dr. Thackeray's spirited proposition does not seem to have been generously responded to, for at the fifth anniversary meeting at Cheltenham in 1837 the Council reported under the heading "Prize Essay":

"No further contributions have been received for the Prize Essay Fund, but the Council have to announce that Dr. Thackeray has increased his already liberal donation to fifty pounds, to be given as a prize for the best essay on a medical subject to be fixed upon at the anniversary meeting at Cheltenham. The prize, which the Council propose shall be called the Thackeray Prize, to be open to the competition of the members of every accredited school of medicine and surgery in the United Kingdom, and the essays to be sent to the secretaries one month previous to the anniversary meeting in 1838."

Apparently some delay occurred in carrying out the Council's wishes, for it was not till the meeting at Southampton in 1840 that Dr. Forbes was able to announce "that in pursuance of the liberal intention of Dr. Thackeray, who two or three years ago had offered a prize of fifty pounds to the author of the best essay 'on the causes of the continued fevers of Great Britain and Ireland and the circumstances which may have a tendency to render them communicable from one person to another,'" eight essays had been sent in during the past year. Some of the essays were of high merit, and the judges had difficulty in adjudicating. Finally, Dr. Davidson of Glasgow was awarded the prize.

This was not the only benefaction of Dr. W. M. Thackeray, who was physician to the Chester Infirmary from 1798 to 1849, in which year he died. By the kindness of Mr. J. Rowse Mitchell, secretary to the Chester Royal Infirmary, we learn that in 1846 he made a gift to the Infirmary of 100 guineas, to be invested and the interest to be devoted to the annual purchase of [illegible] to be kept in the Infirmary for the use of all practitioners in the neighbourhood, "in grateful recollection of the confidence and kindness I have received for more than half a century in this city and neighbourhood." He also made a deed of gift of his library to the Infirmary. The Thackeray Medical Library Trust is still maintained, and the board of management contributes to its support. It is housed in the Infirmary building and managed by two librarians—one the house-surgeon, appointed by the medical staff, and the other by the board.

Dr. William Makepeace Thackeray of Chester was a son of Dr. Thomas Thackeray of Cambridge, who had fifteen or sixteen children, of whom four were members of the medical profession—namely, Thomas, who is said to have "retired with an ample fortune from the service of the India Company"; William Makepeace of Chester; Frederick, physician to Addenbrooke's Hospital, Cambridge; and Joseph, physician to Bedford Infirmary, who died in 1832, and of whom a long biographical memoir appeared in the same volume of transactions in which his brother's offer of a prize was recorded.

This memoir of twenty-four pages is a good specimen of the fulsome elegy of that day, but it shows clearly that Joseph Thackeray was a typical good physician, although, as his biographer wrote:

"It is illustrative of the present state of the profession of physic, that though he was eligible to the highest honours of the London College of Physicians, even under its own antiquated by-laws, he never connected himself with that learned body by becoming either a Fellow or Licentiate."

He was a scholar and Fellow of King's College, Cambridge, and studied at Edinburgh and Glasgow as well as London. He seems to have devoted himself to the Bedford Infirmary, to which he and his wife and mother-in-law, the last being the widow of one of its surgeons, gave sums amounting to "not less than £2,500." Through his efforts a chaplaincy was endowed, and a fund established for pensioning hospital servants. He was active in removing restrictions on admission and so making the infirmary a general hospital, and he established a library and museum, giving to it 400 books from his own medical library. His biographer says that he had an extensive and lucrative practice,

"which left no leisure for literary research; and it does not appear that he devoted much time either to general literature and general science. The same causes militated against his cultivating the science which he more immediately professed, so as to extend its boundaries by new discoveries or essential improvements."

His friends and admirers, to the number of 370, subscribed to have his portrait painted by "the late Mr Jackson," no doubt John Jackson, R.A., whose work is well known, and who died in 1831. The portrait now hangs on the wall of the hall of the County Hospital at Bedford. An uncle of these four brothers was Dr. Frederick Thackeray, a physician at Windsor.

All these Thackerays were descendants of the Rev. Thomas Thackeray, head master of Harrow and archdeacon of Surrey, who, like his son Thomas, had sixteen children. The novelist—William Makepeace the third—was the great-grandson of the archdeacon through his son William Makepeace the first, who had twelve children, for the Thackerays in the eighteenth century were a prolific stock. It is clear that the author of *Pendennis* and *Philip* had extensive medical connexions, and he has shown his understanding of medical men in his books, particularly in the magnificent tribute which he paid in the character of Dr. Goodenough in *Philip*, no less than in his characterization of a medical humbug and villain in the person of Dr. Brand Firmin.

England and Wales

Court Dinner of the Society of Apothecaries

ie Court dinner of the Society of Apothecaries on igust 18th was memorable because of the recent retire-ent of Lieut Colonel C T Samman from the post of aster, which he had held for three years, a tenure ipreceden ted in the history of the society During this nod a considerable amount of work has been done part from the formation of the register of biophysical sistants, Apothecaries' Hall has been extensively restored ving to damage caused by the death watch beetle The ew Master is Colonel E C Freeman, who was the nior warden last year In the course of the Court inner Dr C Wakefield recalled the fact that Colonel amman had continued to reside in Ireland for three ears after joining the Court of Assistants in 1927, but ad not missed a meeting of it, and many other eferences were made to the interest and practical help which had always been forthcoming from him Dr Milton Townsend presented to the society, through the Master a loving cup which had been in the possession of his family since 1789, this he did in memory of his father who had been Master in 1914 The cup bears the following inscription 'A commemorative of the esteem and affection of the subscribers of the Dissenting Meeting House at Stoke Newington towards their worthy Pastor, the Rev Meredith Townsend' Mr H de Vere Stacpoole, responding to the toast of "The Guests," said he was one of the oldest licentiates of the society Commenting on the great changes which had occurred in medicine, he remarked that the number of diseases seemed to have increased alarmingly, and there was also a new range of drugs Professor McCrae of Canada emphasized the fact that the tie between the Mother Country and the Dominions was one of sentiment rather than of business Professor Hunt of the United States was also present as a guest During the evening warm tributes were paid to the work of the late Professor W E Dixon and Dr B Taylor, both of whom had been members of the Court

Venereal Diseases Service in London

The staff employed at the Whitechapel venereal diseases clinic at the London Hospital, in the service of the London County Council, have up to the present been engaged in a temporary capacity, because of uncertainty in regard to the tenancy of the premises used for the purposes of the clinic The Council has now entered into a lease for the utilization of a portion of the London Hospital for the diagnosis and treatment of venereal diseases for the next seven years, and has decided to fix the establishment of staff and scales of salaries It is considered, however, that the medical staffs should continue on a part time and temporary basis so as not to preclude its members from taking private work, exclusion from which would have a prejudicial effect on the type of officer employed It is suggested that thirty six hours a week should be the definite minimum prescribed for the medical staff at the clinic At present thirty three persons are employed, including director, eight assistant medical officers, clinical assistants, a pathologist, and assistant pathologist Having regard to the constantly increasing attendances at the clinic, two more junior assistant medical officers, as well as additional lay staff, will be required before the end of the year The maximum rates of salary are to be for the director, £1,000 a year, for two chief assistant medical officers, £750, for four junior assistant medical officers, £500, for three clinical assistants, £250, for the pathologist, £800, and for the assistant pathologist, £500 The director is required to supervise the treatment of patients referred from the clinic to St Peter's Hospital, Whitechapel, where the in patient beds for the clinic are at present provided, and he is to act as consultant for venereal diseases not only in connexion with St Peter's, but also for eight venereal diseases units about to be established in the Council's general hospitals This consulting work, when all the units are established, will occupy approximately two sessions, each of two and a half hours duration a week The work at St Peter's and Bethnal Green Hospitals (at Bethnal Green women patients from the clinic will be received as in patients) will however, make the greatest demand upon the services of the director, who is to be paid an additional sum of £125 a year in his capacity as consultant, this remuneration being increased to £250 a year when all the units are established

Moorfields Hospital

In the annual report for 1930 of the Royal London Ophthalmic Hospital (Moorfields) it is announced that the first portion of the programme of enlargement and reconstruction has been completed at a cost of £41,365, a new private ward unit and two additional blocks for the nursing and domestic staff having been opened last December The private ward unit comprises seventeen rooms for paying patients, and an operating theatre It is hoped during the present year to extend the existing out patients department, and in the building thus erected to provide additional accommodation for the medical school, including a larger lecture hall, extension of the bacteriological and pathological laboratories, allocation of separate accommodation for the physico therapeutic department, the setting apart of a chapel, and the provision of a new and larger library and museum Although the wards on the existing third floor have been out of use during almost the whole of the past year, 2,555 patients have been admitted, a figure which compares favourably with those of previous years So large a number of admissions has been rendered possible by reducing the length of individual stay in the hospital With the completion of the private ward block, the re opening of the third floor, and the provision of a children's isolation ward, the number of available beds has now been increased to 152 During last year 52,272 new out-patients were dealt with, a larger number than in either of the two previous years Other improvements and additions effected last year include the construction of a second operation theatre for general ward patients, the installation of a modern fire alarm system and fire escape doorways and staircases from the three wards at the eastern end of the building, and the provision of a house surgeon's examination room on the third floor There was a surplus of £1,798 on the year's working, and £13,500 is available towards the second portion of the extension scheme which, as previously outlined, will cost about £40,000 The draft plans for this have already been under consideration, and it is hoped that the adoption of the final plans will not be long delayed

Home Ambulance Service

In its report for the quarter ending June 30th, 1931, the Home Service Ambulance Committee of the Order of St John and the British Red Cross Society mentions that over a million patients have now been carried since the service was instituted in 1919 It is noteworthy that half of this number has been carried during the last four years, although the vehicles employed were fewer by fifty owing to the establishment of municipal ambulance services Considerable improvement in methods of transport has enabled sick persons to be conveyed in comfort often long distances, to hospitals and nursing homes where the latest equipment for diagnosis and

treatment is available. Seven years ago the average number of patients carried per ambulance was 180; last year it was 342. The report again emphasizes the voluntary basis of the service. Each station sets aside every year a small sum towards the cost of replacing the ambulances, and the central committee contributes as much as possible from the resources at its disposal. For the rest it has to depend on the generosity of the public. The total number of ambulances in the service at the end of June was 324, including 115 affiliated stations.

The Liverpool Child Guidance Clinic

The Liverpool Child Guidance Clinic is the only existing fully constituted body of this kind outside London, and a comprehensive account of its work and objectives is contributed to the current issue of the *Liverpool Medico-Chirurgical Journal* by Dr. A. A. Fitch, who is secretary of the Child Guidance Council in that city. He contrasts the work at this clinic with that at similar institutions in the United States, pointing out certain modifications consequent on the existence in this country of a uniform school medical system which is at present absent on the other side of the Atlantic. In Liverpool special attention is devoted to the training of parents; the education of adolescents, as regards conduct and vocation; close co-operation with teachers and the educational authorities in dealing with "problem cases," in the organization of curricula, and in the provision of special types of education; advisory action in conjunction with magistrates of juvenile courts and probation officers; the integration of social services for children—medical, sheltering, reformative, and recreational; and the formation of a general bureau of mental hygiene for collecting and distributing information, and for propaganda. Emphasis is laid on the preventive side of this work, and the importance of bringing about closer co-ordination of those able to assist in any way. The clinic provides a link between the medical practitioner who detects mental disability in the child, and the education authority who can take an active part in securing the continuance of the necessary treatment. The way in which this is done is described, and three broad groups of cases are indicated—namely, dependent children who because of some disaster in the home have to have their lives guided by social agencies of some kind; those whose mental equipment is abnormal; and those who present behaviour problems in all degrees from the mild to the grave. In short, the clinic aims at remedying any deficiencies of the home or school by seeking to bring about a better social adjustment of individual children during their early formative years.

Scotland

Laboratory of Royal College of Physicians, Edinburgh

The annual report presented by the curator, Sir Robert Philip, shows that during 1930 the resources of the laboratory have been utilized to the full. In the research department twenty-three investigations have been undertaken by eighteen research workers, and fourteen papers and two articles have been published. These include statistical researches into general epidemiology and into the epidemiology of kala-azar by the superintendent, Lieut.-Colonel A. G. McKendrick, I.M.S., and by Dr. W. O. Kermack, and into antirabic treatment (at the instance of the Health Section of the League of Nations); a histological study of the normal breast during its various phases of growth and activity, and of cancer of the breast, by Mrs. J. W. Dawson, in association with the late Professor J. Lorrain Smith; further development of the "Cabinet Gallery" of tumours, by Lieut.-Colonel W. Harvey and Mr. T. D. Hamilton; observations on rhinthitis in animals, by Dr. J. S. Fraser; experimental work on neuropathology, by Dr. David Orr; a study of haemophilic bacteria in relation to influenza, by Lieut.-Colonel W. Glen Liston; researches in chemotherapy, the Medical Research Council), and the colloidal chemistry of immunology, by Dr. W. O. Kermack and his co-workers; studies in gastric secretion, by Dr. T. C. Mitchell; experiments on the effect of various agents on the physical condition and digestibility of milk, by Dr. Douglas Nicholson; and a mathematical inquiry relating to Professor Whittaker's new theorem in partial differential equations, by Drs. Kermack and McCrea. The reporting department has had to deal with a further increase of work. During the year 14,936 reports were prepared, 3,235 involving histological examination, 9,671 bacteriological, and 2,630 chemical. The excess of expenditure over ordinary income has been met, as in former years, by a grant from the Carnegie trustees.

Scottish Vital Statistics

The Registrar-General's report for the quarter ending June 30th, 1931, states that the number of births, 24,122 (rate, 20 per 1,000 of the population), is 1,285 fewer than the average for the second quarter. Deaths numbered 15,918 (rate, 13.2 per 1,000), which is 316 less than the average. There were 1,867 deaths of children under 1 year, equivalent to a rate of 77 per 1,000 registered births. Deaths from violence amounted to 659, and of these 153 were due to accidents from motor vehicles, which is 38 more than were recorded in the previous quarter.

Central Midwives Board

Out of 136 candidates who appeared for the recent examination 125 passed. Of the successful candidates, 38 were trained at the Royal Maternity Hospital, Glasgow; 27 at the Royal Maternity Hospital, Edinburgh; 5 at the Maternity Hospital, Aberdeen; 12 at the Royal Infirmary, Dundee; 10 at the Elsie Inglis Hospital, Edinburgh; 12 at Bellshill; and the remainder at various recognized institutions.

Edinburgh Royal Infirmary Extension Appeal

The subscriptions received in response to the managers' appeal for £500,000 now amount to some £214,000. It is of interest to note that the largest recent contribution consists of the proceeds from the Command performance of *The Admirable Crichton* by the Masque Theatre Company at the Lyceum Theatre, Edinburgh, on July 11th, amounting to £2,924.

The Royal Samaritan Hospital for Women, Glasgow

The annual medical and clinical report for 1930 of the Royal Samaritan Hospital for Women, Glasgow, includes a compilation of the medical statistics of patients, whose clinical conditions are classified under four headings, regional lesions, general diseases, morbid processes out-side the genital and urinary tracts, and lesions not classifiable in the three previous groups. According to the practice introduced last year the medical statistics are again published separately from the ordinary annual report of the institution, and the hope is expressed that they will be found useful to general practitioners as well as to obstetricians and gynaecologists. The total number of patients treated in 1930 was 2,860, and 2,537 operations were performed, the percentage mortality rate being 1.36. It has not yet been found possible to correlate details of operative and other forms of treatment with the pathological conditions present in each case, although it is admitted that a mere list of operations by itself conveys little information of practical value. As regards the etiology of

conditions dealt with, it is noteworthy that in no ver than 972 out of the total 2,860 cases parturition was ociated with maternal injury, while infection incurred at at time was a causative factor in 866 cases. A tumour cyst was present in 611 instances, and developmental ors were traced in 215. Brief notes are appended of ses which terminated fatally.

Ireland

Immunization against Diphtheria in the Borough of Cork

The annual report of the medical officer of health for the County Borough of Cork for the year 1930 refers to the value of immunization in the prevention of diphtheria. The report states that during the past year 588 cases were notified. In April, 1930, a survey was made of the children who had been immunized in the previous year. Immunization was started in June, 1929, and by the end of the year 1,802 children had been treated. Altogether 12 of these were subsequently reported to be suffering from diphtheria, and each case was investigated. Ten were eliminated for the following reasons: (*a*) four had not completed treatment (three had only one injection, and one only two); (*b*) in three cases a period of less than four months had elapsed (in two cases only one month, and in one case only two weeks); (*c*) in three other cases the diagnosis was not confirmed. Thus out of a total of 1,802 children who received inoculations two subsequently developed diphtheria, which is equivalent to an incidence rate of 1.11 per 1,000. In the same year 298 cases of diphtheria were notified among the child population (under 15 years) of 22,605, or a ratio of 13.18 per 1,000; no case occurred among children who had been Schick-tested after treatment and were known to be negative. During the year there were 238 notifications of scarlatina, the highest number since 1926. Eight deaths were registered as due to the disease, which is equivalent to a case mortality of 3.4 per cent. As whooping-cough is not notifiable, it is impossible to state exactly the incidence of this disease, but it is evident that there must have been a considerable number of cases, as 35 deaths were registered during the winter of 1929–30. There were no cases of typhus or typhoid fever during the period under review.

Panel Patients in Northern Ireland

At a recent meeting the Dungannon Urban Council discussed its liability in connexion with the treatment of panel patients in hospitals other than the Dungannon Union Hospital. It was mentioned that among the accounts was a fee for the ambulance driver for conveying a panel patient to the Tyrone County Hospital. The clerk explained that the fee was in order, as the dispensary medical officer had received a visiting ticket for the patient. The council had decided to be responsible for the treatment of dispensary patients in Belfast and Tyrone County Hospitals, but that did not include panel patients. In regard to the institutional treatment of panel patients, a letter had been received from the Ministry stating that no distinction could be drawn between panel patients and other patients. It was the duty of the Urban Council to make arrangements for such treatment on behalf of any person who was unable to obtain it himself, subject to the deduction of such an amount as the council considered the patient able to pay. With reference to the responsibility for payment of the ambulance driver's fees for conveying patients from Dungannon urban district to hospitals other than the Union Hospital, the Ministry replied that if it was necessary to send patients from Dungannon urban district to any hospital other than the Union Hospital, responsibility for making the arrangements lay with the Dungannon Urban Council, and that that body should obtain the Ministry's consent, under Section 3 of the Local Government Act (Northern Ireland), 1923, to the payment of the necessary travelling expenses. The clerk said that there was no Act of Parliament that he could find which made it compulsory for the Urban Council to do anything of the sort. He had made inquiries and found that Armagh, Portadown, and Cookstown did not send any patients for institutional treatment. All that was done by the respective boards of guardians, and was paid for out of the poor rate. The council decided that the Ministry should be asked under what section of the Local Government Act (Northern Ireland), 1923, the Urban Council was liable for the institutional treatment of panel patients, or for their conveyance to outside hospitals. The motion was unanimously passed.

Hospital Sweepstakes

At its last meeting the Dublin Union Committee considered a circular letter from the Department for Local Government and Public Health, accompanied by a copy of Section 6 of the Public Charitable Hospitals (Amendment) Act, 1931, relating to the application of part of the proceeds of sweepstakes to Poor Law hospitals. The letter stated that the section imposed on the Minister the duty of applying such money as might be available towards the provision, improvement, or equipment of institutions, and towards the prevention, treatment, or cure of physical and mental diseases. It was expressly provided that money so applied should be in addition to, and not in substitution for or towards, ordinary maintenance, and should not be taken into consideration by the local authority when determining the amount to be expended by it; further, that the application of the money might be conditional upon the fulfilment of such conditions as the Minister thought proper to impose. Decisions with regard to the application of the money would not be taken until the exact amount to be distributed was known. In the meantime it would be convenient if each local authority intending to provide, improve, or equip an institution, and to apply for a grant out of the money to be paid to the Minister, would transmit to the department before October 19th next particulars of its proposals. It was decided that the resident medical superintendent, after consultation with the medical staff, should submit proposals for the consideration of the committee.

Correspondence

"A SYSTEM OF BACTERIOLOGY"

SIR,—The review of volume viii of this *System*, published in the *Journal* of August 15th, contains the surprising statement that "in Weil's disease the leptospirae exhibit a variety of serological types . . . which the author omits to mention." It is not clear whether the reviewer is using the term "Weil's disease" for all febrile conditions associated with the presence of leprospira in the blood, or in its more usual restricted application for infectious jaundice, caused by a particular strain of leptospira generally known as *S. icterohaemorrhagiae*; but, since the pathogenic strains of leptospira are distinguished entirely by their serological reactions, it would seem that the reviewer must have adopted the first interpretation. The most cursory examination of my brief account of infectious jaundice and other leptospiral infections (pp. 301–14) would have shown that I not only refer

to some of these different serological types, but actually retain the names that have been applied to them, such as *Spirochaeta* (*Leptospira*) *autumnalis* (p. 312), *hebdomadis* (p. 313), and *pyrogenes* (p. 314). Moreover, I conclude with the statement (p. 314) "that Fletcher isolated six serologically distinct groups of spirochaetes from patients in Malaya, all showing very similar clinical symptoms.—I am, etc.,

London, N.W.3, Aug. 15th. EDWARD HINDLE.

We have submitted the above letter to our reviewer, who replies as follows:

In his excellent article on the leptospiroses Dr. Hindle makes it perfectly clear that the pathogenic leptospira comprise a variety of serological types and that, in fact, by their serological reactions alone can they be distinguished from one another. The remarks to which Dr. Hindle takes exception were made in view of the work of Taylor and Goyle on epidemic jaundice in the Andaman Islands. The condition investigated by them and referred to as Weil's disease possessed all the clinical manifestations and post-mortem appearances of that disease. Further, its epidemiology was that of Weil's disease, in that the cases occurred principally in the wet season—the south-west monsoon—and were confined exclusively to a certain class of individuals—namely, adult males whose occupation entailed wet working conditions. The twenty-eight strains of leptospira isolated by Taylor and Goyle in the Andamans were compared serologically with a representative collection of leptospira from different parts of the world, including *S. icterohaemorrhagiae*. Not one of the twenty-eight strains corresponded serologically with *S. icterohaemorrhagiae*; twenty-four of them differed apparently from any known strain, although forming a homogeneous serological group themselves; the remaining four were serologically related to *S. autumnalis* (Akiyami Type A). These workers further claimed that, from their examination of the various strains of leptospira by cross-agglutination, *S. icterohaemorrhagiae* could be divided into two groups, which they designated A and B. A point overlooked when writing the review was that Dr. Hindle's article had probably gone to press before Goyle and Taylor's work appeared, in which case the criticism of his article was not valid, and an apology is due to him. He might, of course, contend that, since the leptospira isolated by Taylor and Goyle were not serologically identical with *S. icterohaemorrhagiae*, the condition they were investigating was not Weil's disease. It is with considerable hesitation that one questions the opinion of Dr. Hindle on this subject, of which he is an acknowledged authority, but it does seem that narrowing the definition of Weil's disease in this way would be almost comparable to confining the term lobar pneumonia to those pneumonias caused by the Type I pneumococcus.

CONVULSIONS DURING ETHER ANAESTHESIA

SIR,—The following case occurred at Victoria Hospital, Burnley, on August 5th.

A schoolboy, aged 11, was operated upon by Mr. Callam for a gangrenous pelvic appendix, with abscess. The condition began about sixty hours before admission. He had on admission a temperature of 103° F., a pulse rate of 120, rigidity of the lower abdomen, and marked toxaemia.

Before the operation he was given 1/150 grain of atropine sulphate subcutaneously. Anaesthesia was induced by C.E. mixture, followed by open ether, and continued with ether and oxygen by Shipway's apparatus. The anaesthesia was uneventful till the operation had been in progress for about forty-five minutes, when convulsions began just as the operator was beginning to close the wound. The convulsions were first noticed in the lower extremities, and became generalized. The pupils were widely dilated and the conjunctiva was insensitive. There was no clonus of the lower jaw, the tongue being rhythmically protruded and withdrawn. There was no cyanosis. Chloroform and oxygen were then given. The convulsions diminished in severity and ceased in about seven minutes—by the time the operation was concluded. On return to bed he recovered normally from the anaesthetic and there was no recurrence of the convulsions. There was no history of epilepsy or of any previous fit, though the boy was of a highly strung, nervous type.

The ether used was Duncan's "anaesthetic ether," which has been in general use in this hospital for years. The same stock bottle had been used just previously, and was used in the next case satisfactorily. Analysis revealed neither ethyl sulphate, ether peroxide, acetaldehyde, nor other impurity. The absence of impurity in the actual sample used, and the fact that the same brand of ether has been in general use daily for years without a previous case occurring, seems to disprove the theory that the condition is due to impurities in the ether.

One is inclined to think that toxaemia and instability of the nervous system are the most probable causes of the condition in this case, and seem to be the commonest factors in previously reported cases.

I have to thank Mr. Lawrie for his analysis of the ether.—I am, etc.,

JAMES HAWORTH,
Senior Anaesthetist.

Victoria Hospital, Burnley, Aug. 17th.

SIR,—The cause of ether convulsions appears to remain a mystery. During my small experience I have made careful observations which may assist in providing a clue.

Toxaemic patients seem most prone to convulsions, and then only if oxygen is given with the ether. Convulsions apart from oxygen are probably clonus. Toxaemic cases commonly met with are appendices in the gangrenous stage, osteomyelitis, salpingitis, infected compound fractures, etc.

An explanation of convulsions on a physiological basis is beyond my powers; however, the sequence of events leading to convulsions is easy to follow. The induction of a toxaemic case is of the easiest, and deep anaesthesia is quickly attained. Deep anaesthesia, in spite of a perfect airway, causes cyanosis, and it is at this point that mistakes are made and convulsions occur. Oxygen is promptly given and the signs of convulsions soon become apparent.

Convulsions can be avoided by inducing toxaemic cases with caution. Provided the airway is clear, meet any cyanosis by reducing the dose of ether and by removing the mask if necessary. If oxygen seems essential, give the smallest quantity and remove as soon as the colour is normal. In the treatment of convulsions remove the oxygen at once. If cyanosed, remove the mask as well, and replace when the colour is normal. The convulsions will cease in a time approximately equal to their duration. —I am, etc.,

C. J. BASHALL, M.R.C.S., L.R.C.P.

Marlborough, Aug. 18th.

CARCINOMA OF THE OESOPHAGUS

SIR,—On reading the article by Mr. Woodman in the *Journal* of August 15th on the treatment of carcinoma of the oesophagus, I was struck by his omission of simple dilatation from the methods he discussed. Leaving radical extirpation out of the question of the treatment of this condition, we are faced with palliative measures consisting of radium, *x* rays, diathermy, intubation, gastrostomy, and dilatation. Since one of them is to be chosen, it seems to me that the best method is one

which should most nearly fulfil the following conditions (1) the easiest to carry out from the point of view of the surgeon, (2) the least uncomfortable to carry out from the point of view of the patient, (3) brings the greatest relief, and (4) carries the least risk to life

Bearing in mind these conditions, simple dilatation by the Plummer method seems the most satisfactory of the palliative measures, for, with regard to the first two, it is far ahead of any of the others, it certainly brings no less relief, while, seeing that the dilating olive is passed on a thread which has already wormed its way through the malignant stricture, the danger of perforation, with consequent fatal mediastinitis, is almost negligible Lastly, the expectation of life following this treatment is not likely to be less, and in many cases is greater, than that following the other methods enumerated above — I am, etc,

Newcastle-on Tyne, Aug 23rd JAMES H SAINT

PRURITUS ANI

SIR,—Thanks are due to Dr Macarthur for his extremely interesting paper on pruritus ani in the *Journal* of August 22nd (p 334) My experience is that *Enterobius vermicularis* can escape unaided through the anal sphincters, but that the patient is not conscious of their presence until they have emerged outside the internal sphincter I have long been of opinion that these parasites are the cause of diverticulitis, the damage which they do to the intestinal wall originating this disease, but I have not experimentally verified this in animals —I am, etc,

Southampton, Aug 24th A A MACKEITH

A TREATMENT OF WOUNDS IN 1821

SIR —During the war I came across the method of irrigating wounds detailed in the excerpt which I subjoin from an interesting book of travel, *Recollections of West end Life, with Sketches of Society in Paris, India Etc, Etc*, by Major Chambre, during the early years of last century, and which I feel sure will interest many readers I made a reference note, intending to send it along to you at that time, but the reference was lost, and only the other day was I able to find the book It is remarkable that the method was not made more widely known and adopted, for it must have recommended itself to surgeons who saw it in operation

The similarity of this early, pre antiseptic method to that evolved during the war is remarkable I date the visit of the author to Lausanne, as accurately as possible from the context, to be 1821–22

'I must not omit mentioning a visit I paid to the Lausanne public hospital in company with the celebrated surgeon Mayor who was so kind as to show me over the wards He wished to exhibit a method he had of applying cold water to wounds which he requested me to mention to the medical men of the English army whenever I had an opportunity as he thought it might be very useful in campaigning A bucket was suspended from the ceiling in the centre of the room In this holes were bored with a gimlet and strings were passed through them the ends of which were placed on the wounds of the patients It did not signify how many there were because when the bucket was filled with water it trickled down them in whatever direction they were placed The only trouble attending the process was to keep up the supply of water I spoke to the sufferers to ascertain the effect of it and they one and all said that it spared them much pain for it entirely kept down inflammation The usual method of applying wet bandages entails a good deal of trouble, and as far as an unscientific person could judge, I thought his plan a very good one"

—I am, etc, W P CORMACK, M B, Ch B

Role, South Australia, July 20th

Obituary

ROBERT MacNEIL BUCHANAN, J P., M B, C M PRFPS

Late City Bacteriologist, Glasgow

We regret to announce that Dr Robert MacNeil Buchanan died at his residence in Glasgow on August 15th after a long illness He was the first city bacteriologist appointed by the Corporation of Glasgow, and assumed this office in 1899, retiring in November, 1930

Dr Buchanan's choice of the career of a scientist was the natural outcome of his earlier training and experience, as well as of his own predilections, and he himself explained the tendency towards comparative pathology which many of his studies took by the fact that he was a son of the farm

After a period at the Glasgow High School, he went into business but it was always his ambition to take up a scientific career He extended his knowledge and widened his interests by attending classes in French, Spanish, and chemistry at the Technical College He became a medical student at the age of 23 and graduated M B C M Glas in 1888, he obtained the diploma F R F P S in 1895 During his undergraduate career he attracted the attention of Professor Joseph Coats, who then occupied the chair of pathology, and to whom he ultimately became assistant obtaining the John Reid Prize in that subject, Dr Buchanan's son recently carried off the same prize After graduation he was awarded the Foulis Memorial Scholarship which enabled him to study pathology and bacteriology at Frankfurt and Berlin under Professors Weigert and Koch At this period the science of bacteriology was in its infancy, and it was the opportunity to study these two allied subjects under such eminent masters which determined Dr Buchanan's future career along lines which were highly congenial to him Returning home, he delivered a course of university lectures, and in 1892 was appointed the first lecturer on bacteriology to the University of Glasgow, as well as first assistant to the professor of pathology The laboratory at this stage was comprised within the walls of a room 10 feet square The part played by bacteria in the causation of disease was still to a great extent unknown, although generally suspected, and the work of the young bacteriologist in his small room attracted the attention of such men as Sir William Gairdner, Sir Hector Cameron, Professor Samson Gemmell, and also of Dr J B Russell, who was then medical officer of health of the city He next occupied the chair of medical jurisprudence and hygiene in Anderson's Medical College, where he established the West of Scotland Clinical Research Association, an organization which still exists although much of the work it was intended to perform is now carried out in the great laboratories of the voluntary hospitals of the city, and in those of the corporation

Dr Buchanan commenced his duties as city bacteriologist in a single room fitted up for the purpose, with the use of another room in the tower for the preparation of

culture media. The speedy growth of applied bacteriology caused this department to assume a more and more prominent place in public health and prevention of disease, until, under his guidance, there arose that important department where a great variety of scientific duties is now performed on behalf of the corporation and the public. One of his first important duties was in connexion with the outbreak of plague in 1900-1, when he was associated with the professor of pathology in discovering, after long and tedious search, the source of plague in the rats which infested a particular area of the city. Dr. Buchanan himself demonstrated the presence of the plague bacillus in the rat flea. He was thus able to assist in coping with the spread of this serious disease, which might have involved the city in more disastrous consequences than it actually did. He took the extreme risk of performing the necessary post-mortems without the aid of gloves, which were of so coarse a texture as to hamper the delicate manipulations necessary, a proceeding which called forth a protest from a German scientist who was watching him: "Gott bewahr, Herr Doktor." Another of his achievements was the eradication of glanders from the horses of the tramway department, and the laboratory contains the finest series of specimens of this affection in the country. He was called upon to deal with many epidemics, such as that of cerebro-spinal fever in 1906, and various outbreaks of typhoid fever. His laboratory also performs a great variety of routine investigations, ranging from the examination of milk and Loch Katrine water to the diagnosis of insect pests, of which there are about sixty different species to be found in the vicinity.

In addition to his bacteriological work, one of the chief features of Dr. Buchanan's activities was his interest in comparative pathology. He made it manifest in 1922 that much gain could be expected from the correlation of disease processes in man and in the lower forms of life. His interests in this respect led him into such questions as the diseases associated with the vegetable and animal world—diseases of great economic importance—such as the blights affecting various fruits, and the diseases of such foodstuffs as the potato, the currant, the tomato, the apple, and other vegetable products. Dr. Buchanan also showed for many years a strong liking for the study of the insect world. This study was of interest to him both because of its intrinsic appeal and because of the serious economic loss entailed by the destructive activities of many insects. His wide knowledge of the life-histories of insects was consequently of great value, and his advice was commonly sought from all over the country with regard to their identification, their habits, and the methods to be adopted for their extermination. For a number of years he had been greatly interested in the causation of grass sickness in horses, because of its similarity to encephalitis in man. The museum which he instituted in the laboratory has proved of the utmost value to sanitarians and of unfailing interest to lay visitors. Dr. Buchanan published numerous papers dealing with his particular subjects, and had been, in fact, accumulating material for a book dealing with one particular aspect of the many he had studied during his long experience.

On the more personal side, Dr. Buchanan was held in the very highest esteem by his colleagues in the medical profession. In 1925 he received the highest honour which the profession, in its own city, has in its power to bestow, the Presidency of the Royal Faculty of Physicians and Surgeons. He occupied this post with distinction for two years, during which he was called upon to organize the celebrations in connexion with the Lister Centenary, high duties which he performed with dignity and success. In this appointment history has exemplified its habit of repeating itself, though after a long interval, for Maister Peter Lowe, who founded the Faculty in 1599, himself held an official post as surgeon to the corporation. On the occasion of the Pasteur Centenary in 1922, Dr. Buchanan was asked to deliver an oration on Pasteur at the request of the Royal Philosophical Society.

Dr. Buchanan took great interest in the work of the British Medical Association; he was chairman of the Glasgow North-Western Division from 1925 to 1927, and president of the Glasgow and West of Scotland Branch in 1928-29. He was also a representative of the Glasgow Division in the Representative Body for 1929-30, and president of the Section of Microbiology (including Bacteriology) when the Association held its Annual Meeting in Glasgow in 1922.

Although he retired from the services of the Corporation of Glasgow in November, 1930, his colleagues had looked forward to availing themselves of his exceptional and specialized knowledge for many years. His services to the city, love for his work, and the prominent position he occupied by virtue both of his office and of the universal esteem in which he was held by his fellows, are a measure of the loss which the city of Glasgow has sustained by his death. He was a man of charming personality, and ever willing to assist his younger colleagues. Deep sympathy is extended to his widow in her bereavement.

[The photograph reproduced is by T. and R. Annan and Sons, Glasgow.]

GROUP CAPTAIN MARTIN FLACK, C.B.E.,

M.A.Oxon., M.B., B.Ch.Oxon.

Group Captain Martin Flack, director of the department of medical research for the Air Ministry, died in the Royal Air Force Hospital, Halton, on August 16th, in his fiftieth year. Four months ago he became subject to attacks of pyrexia of obscure origin and entered the chief hospital attached to his Service for observation and treatment. His illness proved to be a form of septicaemia, and, in spite of the skilled attention and the loving care of his colleagues, who were deeply attached to him, and the application of the best means available, he ultimately succumbed—in spite of great natural strength of body and will—to his malady. He did much that will be remembered both for medicine and for the Service to which he was attached. To him was entrusted the responsible task of establishing a research service under the Director-General of the medical department of the Royal Air Force in the later years of the great war.

Martin Flack was born in the village of Borden, Kent, and had to make his own way in life. Scholarships and home help carried him to Keble College, Oxford, which he entered as science exhibitioner in 1901, being then 19 years of age. Applying himself to medical subjects, he came under the influence of Professor Arthur Thomson and the late Professor Francis Gotch, from whom he imbibed the spirit of inquiry. One other man had a profound influence on him—as on many Oxford men—the late William Hatchett Jackson, a Fellow of Keble

and Radcliffe Librarian Jackson taught him how a good life should be spent

In 1905, having taken his B A degree, he entered the London Hospital, obtaining the Price Scholarship, Although his work lay in the hospital, his scientific inclinations took him frequently to its medical college, where his great natural abilities were recognized by Sir Leonard Hill, then lecturer on physiology, and by Sir Arthur Keith, who taught anatomy in the college of the London Hospital At that time Sir Arthur Keith was making an inquiry into the arrangement of the musculature round the venous orifice of the auricular chambers of the heart, and was joined by Flack in this inquiry In the following year (1906), Tawara announced his discovery of a system of conducting musculature between the auricles and ventricles of the mammalian heart Keith and Flack at once verified the truth of Tawara s discovery and set out to trace the evolution of the mammalian auriculo ventricular connecting system from the simpler arrangement found in the hearts of lower vertebrates, and also to ascertain if in the region where the heart beat was believed to begin—namely, at the termination of the superior vena cava in the right auricle —there existed tissue of the nature of the node which Tawara discovered at the beginning of the auriculo ventricular bundle They found in all mammalian hearts, at the expected site, a collection of peculiar muscular tissue, which they named the sino auricular node, in forming from its position, and from its resemblance to the tissue at the beginning of the ventricular bundle, that this node was concerned in the inception of the heart beat Four years later (1910), Flack, when working in Professor Kronecker s laboratory in Berne, carried out experiments which supported this contention The credit of demonstrating the exact site at which the normal heart beat begins, and of proving that the site coincides with the position of the sino auricular node, belongs to Sir Thomas Lewis

While carrying out his clinical studies in the wards of the hospital, Flack acted as assistant demonstrator of physiology under Sir Leonard Hill, and assisted his chief in the many researches which were then being conducted in the department—researches which, in the main, related to fundamental problems of circulation and respiration In this way he gained a first hand knowledge of the regulatory mechanisms of the heart and lungs, a knowledge which he applied afterwards with signal success in solving the medical problems of aviation

In 1908, at the age of 26, he became M B , B Ch Oxon , M A Oxon , and married his cousin, Cecile Cooper His income as demonstrator of physiology at the London Hospital was then £150 per annum On this slender income debts contracted for his education were paid off, a happy household was established, to which in due time two sons and two daughters were added Martin Flack was a ' sportsman " in the best sense of that word— a man who welcomed life s handicaps, who enjoyed his work, his home, his life, and was ever ready to lend a helping hand to whomsoever might need it Everyone who worked with him enjoyed his partnership , he was resourceful cheerful, with a brave heart, and met his disappointments with a smile In 1909 he was awarded the Radcliffe Travelling Scholarship by his old university, which gave him the opportunities he had longed for—of working in Continental laboratories He worked, as has just been mentioned, in the laboratory of Kronecker at Berne, and also in the same laboratory with Dr L Asher, in a successful investigation on the nerve supply to the thyroid gland He also worked at the heart with Professor Fredericque at Liege Returning from the Continent, he resumed his demonstratorship in Sir Leonard Hill's department, and shared in the many investigations which were being conducted there He wrote the article on the heart for Hill's *Further Advances in Physiology* (1909) , contributed, in conjunction with Professor J J Macleod, the article on physiological chemistry to Pembrey's *Practical Physiology* (1910) , and wrote, in partnership with Sir Leonard Hill, *A Textbook of Physiology* (published in 1919) In 1915 he was awarded the Radcliffe Prize by Oxford University At this time Sir Leonard Hill was called on to establish a department of applied physiology for the Medical Research Council Flack accompanied his chief to Mount Vernon, and it was while so engaged that he was appointed to take charge of the department of medical research, which the Air Ministry had established under the Director General of the Medical Service of the Royal Air Force

No happier choice could have been made He threw all his energies into his new office The problems he had to solve were of two kinds what were the causes which had led to the breakdown, both in body and in mind, of experienced flyers? how could candidates for the Royal Air Force who were constitutionally unfit for flying be detected? His training in physiology and his experience as an investigator stood him in good stead He devised a series of tests for the detection of physical inefficiency and of physiological instability These tests, the methods of their application, and the results which flying experience brought to light, were made the subject of his Milroy Lectures at the Royal College of Physicians in 1921. Further contributions from his department will be found in the pages of the *British Medical Journal* (" Estimation of physical efficiency," 1923, ii, 921 , " Note on sea sickness," 1931, i, 176) He contributed also the article on the medical problems of aviation to the *Encyclopaedia Britannica* , an article on ' Applied physiology of aviation " to Dr H Graeme Anderson's *Medical and Surgical Aspects of Aviation* (1919) , on ' Stable nervous control in relation to flying (*Lancet* 1925, ii, 1748) and another on " Man and the machine ' to *Military Surgery* (1927, lxi, 758)

At the close of the war his important services were recognized , he was mentioned in dispatches, and received the honour of C B E His enthusiasm was infectious , he knew how to give willing service, and he knew how to obtain it For the welfare and improvement of the department to which he was attached he gave all that was in him No trouble was too much He was an educator, and took every opportunity of addressing men of the Royal Air Force on matters relating to the maintenance of health, of physical efficiency, and of morale None will feel his loss more deeply than those who were associated with him in the headquarters of the medical department of the Air Ministry The sympathy of all will go out to his widow and his four children in their grievous loss

Sir Leonard Hill writes

Martin Flack was a man of high courage and great ability Born in a Kentish village, of a father who could give the weight of a score of live beasts correctly within a few pounds, he raised himself to Oxford University by the winning of scholarships, and won through to the taking of his medical degrees, but hampered with a debt to pay off when he first earned a demonstrator s salary under me Working first with Arthur Keith he discovered anatomically the sino auricular node and then showed experimentally on living animals that this actually was the pace maker of the heart The brilliant after work of Sir Thomas Lewis to some extent obscured Flack s discovery and the world as the excellent appreciation of him in the *Times* of August 19th shows, did not fully realize the fact that he first experimentally proved the function of the node I can well remember projecting,

with his help, the beating heart of an animal on the screen by means of an epidiascope, and showing the whole class at the London Hospital Medical College the startling effect of local cooling on this node. Flack was a splendid and enthusiastic teacher and demonstrator, and he and I together carried out many researches at the London on the effect of want of oxygen and excess of carbon dioxide; in particular, we showed the influence which breathing oxygen had on the power to hold the breath and withstand a notably high concentration of carbon dioxide. We showed that filling the lungs with oxygen just beforehand enabled an athlete to run an unpaced quarter or half mile with astonishing ease and pace, and with no after-feeling of stiffness or fatigue. Flack accompanied Wolffe, the Channel swimmer, on one of his attempts and gave him oxygen when exhausted, and saw him breathe it in from a bag with huge deep breaths, and then start to swim again with astonishing vigour, only at the end, however, to be beaten by the cold, and this within a quarter or mile or so of the French shore. We showed, too, how oxygen given in an interval renewed the vigour of an exhausted boxer. At Eton College an unskilled and exhausted lad, after receiving oxygen, knocked his skilled opponent through the ropes. Flack came with me to the Department of Applied Physiology founded by the Medical Research Council in 1913–14, but when the war demonstrated the need for an investigation into the failure of air pilots at high altitudes, Flack was allocated to this work, and so came to join the Air Service. He now had full opportunity of applying the work we had done together on oxygen want. He not only arranged for the proper supply of oxygen to pilots but also carried out a brilliant set of tests by which he was able to discriminate between pilots who were unfit to fly and those who were fit. Flack's work laid the foundation not only of the medical tests of candidates and pilots, but of physical training for making and keeping pilots fit. He had a genius for applying physiology to such problems.

Flack was troubled with a rheumatic affection of the heart, and as a young man received a grave prognosis; in spite of this he won through, worked very hard, and attained to great ends. A marked characteristic was cheerfulness in the face of all obstacles. At the last he discussed his illness with full knowledge and great courage. We lose in Flack a most cheery, original, and zealous worker, and one of the very best of friends.

Air Vice-Marshal Sir DAVID MUNRO writes:

When I was a Director of Medical Services, R.A.F., I was in close association with Martin Flack, and know better than most the amount of work he did for that Service, and the depth of his loyalty to it. The value to aviation of his scientific investigations into its physiological problems is well known to the world of scientific men, and made him a figure in the world of aviators. In that field of investigation he was in this country the pioneer. Nor was his work known only to his own countrymen: on the continent of Europe and in the U.S.A. workers in the field of medical research, if they had ever heard of the Royal Air Force, knew of it through the name of Flack. Coming to the Service as a trained physiologist, and one who had already made some reputation for himself, Flack's special value to the administration was his grasp of the range of application of physiological principles. He was emphatically a field rather than a laboratory physiologist, and he habitually thought of the everyday actions of human beings in physiological terms. His brain in consequence was fertile in ideas, many of which, if elaborated and written up, would have attracted attention. He always, however, felt strongly that the name of the individual should be subordinated to the name of the Service, and I know that the fear of its being thought that he was trying to gain prominence for himself prevented him from writing up and offering for publication his ideas and findings on many aspects of his work.

I have seldom met a man who had so strong a sense of loyalty, and to the Service which he served so well his loss will be almost irreparable. But it is not only for his knowledge and capabilities that he will be missed; he was, in all his relations, one of the most simple, genuine, and good-hearted of men, and I am sure that there are very many who, like myself, will have experienced in his death a real sense of personal loss.

SAMUEL WILLIS PROWSE, M.D., LL.D., F.R.C.S.Ed., F.A.C.S.

Dean of the Faculty of Medicine, and Professor of Oto-laryngology, University of Manitoba

We regret to record that Dr S. W. Prowse died suddenly from a heart attack in the Winnipeg General Hospital on August 1st, in his sixty-second year.

Samuel Willis Prowse was born in Prince Edward Island, the son of Samuel Prowse, a member of the Senate of Canada. He was educated at Mount Allison University, New Brunswick, and received his medical training in Edinburgh, where he graduated M.B., C.M. in 1893, proceeded M.D. in 1896, and obtained the Fellowship of the Royal College of Surgeons of Edinburgh in 1898. Sir James Purves-Stewart was a classmate, and last year, when the British Medical Association met in Winnipeg, Dr. Prowse had his old classmate as his guest and renewed happy memories. From 1894 to 1898 he practised at Colinsburgh, Fifeshire, and in the latter year he moved to Winnipeg at a time when Canada was entering upon a period of great development. After a year or two of general practice he restricted himself to ophthalmology and oto-laryngology.

In 1902 he became a member of the staff of the Manitoba Medical College, and about that time was appointed to the staff of the Winnipeg General Hospital. In 1910 he was president of the Medico-Chirurgical Society. He took particular interest in the welfare of medical students and of young practitioners, and when the Manitoba Medical College offered to raise a hospital unit in 1916, Dr. Prowse was unanimously selected to act as its head. He was gazetted officer commanding No 4 Casualty Clearing Station, B.E.F., with the rank of lieutenant-colonel, took the unit to France, and while there was appointed dean of the Medical School. His own ill health and the serious illness of his wife compelled him to return to Canada. In a few years the Medical College, an independent institution, though affiliated with the university, transferred to that body its property and equipment, and became the Faculty of Medicine of the University of Manitoba. At a dinner given by his colleagues in 1924, in commemoration of his services as dean, it was announced that his friends had raised £1,000, the proceeds of which were to be devoted to the Prowse Prize for Clinical Research. For many years he was a member of the Royal Society of Medicine; and of the Ophthalmological Society of the United Kingdom. In 1930 he was vice-president of the Section of Laryngology and Otology at the Winnipeg Meeting of the British Medical Association, and at a convocation of the University of Manitoba he received the degree of Doctor of Laws.

To high professional qualifications Dr. Prowse united a courtesy of manner and a dignity of bearing which endeared him not only to his patients and his associates in professional life, but especially to young people. He was singularly unselfish and unsparing of himself, and he carried on the noblest traditions of the profession.

THE LATE PROFESSOR W. E. DIXON

Dr. H. H. DALE, F.R.S., director of the National Institute for Medical Research, writes:

A little more than five years after the sudden death of A. R. Cushny, W. E. Dixon has gone from us suddenly, and at the same age. These two were together chiefly responsible for the rapid rise of activity and interest in pharmacology which has been so manifest in England during the past thirty years. Dixon, the younger of the two, had already been busy with this development for some five years at Cambridge, before Cushny returned from America to London. It is impossible to estimate the effect on a whole generation of Cambridge students of medicine produced by this pioneer work of Dixon in the teaching of pharmacology, and by his stimulating influence on research in that field. Pharmacological teaching in England, when Dixon began, presented an unappetizing mixture of half-obsolete materia medica with empirical therapeutics. In Dixon's hands it became a lively adventure in experimental science, offered with an inimitable racy humour, and a confident enthusiasm. His own scientific interests were wide and unspecialized. For him pharmacology included practically anything on the experimental side of medicine which made contact with therapeutics. This, as others have noted, makes it peculiarly difficult to summarize his work, or to choose any item as his characteristic and outstanding contribution to science. He had an exuberance of ideas, and it was his habit to till widely and sow variously, often leaving others to harvest. A list of additions to knowledge published under his own name, though substantial, gives but a partial idea of his contributions to science, through the many in whom he awakened the desire for research, and to whom he taught its methods. His genial, humorous personality, and his gift of simplification and picturesque emphasis, gave him high repute and authority, not only with his students, but in circles not normally accessible to academic science. There will be many for whom the idea of pharmacology was personified in Dixon, and who will feel the gap caused by his death only less acutely than we who have enjoyed his generous and loyal friendship in the intimacy of scientific association.

Dr. WALTER J. DILLING, professor of pharmacology, Liverpool University, writes:

The untimely death of Professor W. E. Dixon at the acme of his international renown as a pharmacologist is a grievous loss to British scientific medicine and a sad parting to his many intimate friends who delighted in his comradeship.

This is a difficult moment in which to appraise adequately his scientific talents, rare and brilliant as they were; one is, at the moment, overwhelmed by the fact that Dixon, who with tact, courtesy, and outstanding personality has acted as an ideal ambassador of British pharmacology to so many colonial and foreign schools, has fallen with his mission uncompleted. He possessed a masterly knowledge of every detail of his subject, and no matter upon what branch of pharmacology or therapeutics one touched, Dixon had either done some valuable original work upon it or had carefully assessed the literature. Jealous for the reputation of British pharmacology, and keenly judicious, he was enthusiastic in encouraging good work, while his criticisms were couched in terms of kindly and always helpful advice. Possessed of an enviable ability to assess research work rapidly and accurately, yet his generous spirit made him often unwilling to condemn without first seeking confirmatory opinion.

His amazing energies he devoted solely to the advancement of pharmacology and therapeutics by skilfully designed experiments, which always displayed his originality of mind, and by attractive and stimulating lectures. His great breadth of scientific knowledge and organizing ability rendered him an invaluable and wise counsellor on committees of the League of Nations and other organizations concerned with the promotion of the medical sciences.

In nature he was most unselfish and generous to others in both word and deed; many of his juniors unknowingly owe to Dixon remunerative work and appointments for which he recommended them, believing that their monetary needs might be urgent. By the death of Dixon we have lost one of our foremost scientists, who through force of circumstances never achieved the high academic or national honours which he had so abundantly earned by whole-hearted devotion to his subject, his university, and his country.

But it is of Dixon as a warm-hearted friend that many will cherish memories which words fail to express. His charming and buoyant spirit, his joyous love of adventure, and his kindly sympathy and concern for the welfare of others, endeared him to many who will reflect upon many happy hours spent in his society, and sorrow at his passing hence. One's deepest sympathies go out to Mrs. Dixon, who was his inspiration and helpmate in so much that he achieved.

The funeral of the late Professor W. E. Dixon took place at Golders Green Crematorium on August 21st. Among those present in addition to the relatives were: Dr. H. H. Dale (representing the Royal Society); Dr. H. B. Brackenbury, Dr. C. O. Hawthorne, and Dr. Alfred Cox (representing the Council of the British Medical Association); Sir Humphry Rolleston (representing the Cambridge Medical Society); Professor Seward (representing Downing College and the Royal Society); Professor E. D. Adrian (Physiological Laboratory, Cambridge); Dr. M. H. MacKeith (Medical School, Oxford University); Colonel Samman (former Master of the Society of Apothecaries); Dr. J. H. Burn (representing the Pharmaceutical Society); Mr. Owston (representing Cambridge men at St. Bartholomew's Hospital); Dr. F. B. Parsons (representing the Cambridge and Huntingdon Branch of the British Medical Association).

THE LATE LIEUT.-COLONEL LORD

Dr. J. L. BASKIN (Thame) writes:

I have been privileged to know Lieut.-Colonel Lord during the past thirty years; it was through him that I was induced to join the Royal Medico-Psychological Association. He possessed the two qualities most essential for the administration of a mental hospital—namely, sympathy and a firm conception of justice. He was a swift-minded man; the speed of his generalizations was noteworthy, especially as they were based on practical judgement. He spared himself no effort in giving wise assistance to genuine triers after knowledge in the Mental Services, and he will be sadly missed by his medical colleagues.

Dr. JOHN BUCHANAN REID died at his residence in Toronto on May 24th. He was born in Mono Township, near Orangeville, on July 31st, 1861. He graduated M.D. at Trinity College in 1911 and became F.R.C.S.Eng. in 1911. For over forty years he practised at Tillsonburg, where he won the high esteem of all his fellow citizens. Dr. Reid was a member of the British Medical Association. He was an active worker in the temperance movement, and had held several offices in St. Paul's United Church. He is survived by his widow, one daughter, and three sons.

Dr. John O'Callaghan of Pallasgreen, co. Limerick, died on August 4th, after an illness of nine days. He was educated at the Ledwich School, Dublin, and took the diploma of Licentiate of the Royal College of Surgeons in Ireland in 1885, in which year he became L.R.C.P.Ed.; he obtained the F.R.C.S.I. in 1898. After serving as an assistant for a short time at Hull, he was appointed to the Grean Dispensary District, Pallasgreen, co. Limerick, an appointment which he held for thirty years. Failing health caused his retirement some ten years ago. Dr. O'Callaghan was a justice of the peace for Limerick and a member of the North Munster Division of the British Medical Association.

Universities and Colleges

UNIVERSITY OF LONDON

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

The following scholarships and prizes have been awarded:

Entrance University Scholarship: J. D. Fergusson. Hector Mackenzie Exhibition: W. G. Q. Mills. Open Scholarship in Natural Science: First Scholarship, R. R. McSwiney; Second Scholarship, A. W. Wragg, G. A. Hart, A. G. Moore. Open Scholarship in Arts: First Scholarship, W. R. S. Doll; Second Scholarship, T. H. Clifton. William Tite Scholarship: G. W. Hearn, F. C. Durbin.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following scholarships have been awarded for the session 1931-32.

St. Dunstan's Medical Exhibition: Miss Olive M. Singer. Isabel Thorne Scholarship: Miss M. M. Burton. Mrs. George M. Smith Scholarship: Miss Grace E. Reid. Bostock Scholarship: Miss Marjorie F. Landau. Mabel Sharman-Crawford Scholarship: Miss Ruth M. Addison. Dr. Margaret Todd Scholarship: Miss J. C. Goodchild. Special Dr. Margaret Todd Scholarships (two): Miss S. A. M. Herford, Miss J. G. Greenhalgh. Fanny Butler Scholarships (two): Miss M. C. Goodchild, Miss M. A. Powys. School Jubilee Bursary: Miss E. C. Randell. Alfred Langton Scholarship: Miss J. M. Cass. Flora Murray Bursary: Miss H. M. Brown. Ellen Walker Bursary: Miss Q. I. E. May. Helen Prideaux Post-Graduate Scholarships: Miss Ursula Shelley, Miss Beatrice Jolv. Dr. Edith Pechey Phipson Post-Graduate Scholarships: Miss Gulbai P. Patel, Miss Beatrice Board.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—L. F. Donnan, A. K. Guha, J. W. V. Sheldon.

MEDICINE.—V. R. I. Bayhs, G. B. Carter, M. Ditton, E. I. B. Hawes, S. Lokeez, L. R. C. Rose, D. N. Ryalls, E. S. St. John, J. W. V. Sheldon.

FORENSIC MEDICINE.—G. B. Carter, H. W. Davies, B. Dayal, J. M. Durr, S. Lokeez, J. W. V. Sheldon.

MIDWIFERY.—O. A. P. Clark, J. M. Durr, B. N. Halder, S. E. Paterson, D. N. Ryalls, C. F. Vieyra.

The diploma of the Society has been granted to Messrs. G. B. Carter, O. A. P. Clark, A. K. Guha, B. N. Halder, E. I. B. Hawes, S. Lokeez, E. S. St. John.

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel Richard Nugent Stoker, Bengal Medical Service (ret.), died at Duncans, British Columbia, on June 14th, aged 79. He was born on October 31st, 1851, the son of Mr. Abraham Stoker of Clontarf, was educated in Dublin, in the school of the Royal College of Surgeons, and took the L.R.C.S.I. in 1873 and the L.K.Q.C.P. in 1874. Entering the I.M.S. as surgeon on September 30th, 1874, he became surgeon lieutenant-colonel after twenty years' service, and retired on April 2nd, 1900. He served in the Afghan war of 1879, receiving the medal. After the war he was appointed garrison surgeon of Fort Attock, an appointment long ago abolished, and held that post till his promotion to surgeon major in 1876, when he was posted to one of the newly raised Gurkha battalions, with which he served in the Sikkim campaign of 1888 on the North-East Frontier of India, and took part in the forcing of the Jelapla Pass, receiving the frontier medal.

Medical News

The prize distribution and conversazione at the Royal Dental Hospital, Leicester Square, W.C.2, will be held on Friday, October 2nd, at 8 p.m., when Professor Elliot Smith, F.R.S., will preside.

It is proposed to hold a reunion dinner of officers of the No. 3 British General Hospital, Mesopotamia, in London, on October 23rd. Officers of the unit interested in the matter should communicate with Dr. Andrew Topping, Town Hall, Rochdale.

The King Edward's Hospital Fund for London has arranged a river trip to Tilbury Docks on Friday, September 11th. A steam launch will leave Westminster Pier at 9.30 a.m. and arrive back about 6 p.m. There will be a visit of inspection of ss. *Orontes*, on board which a buffet lunch will be served. A representative of the Port of London Authority will accompany the party on a tour of the port and explain its organization and various activities. Tickets for the trip (£1 1s.) can be obtained at the offices of the Fund, 7, Walbrook, E.C.4.

The third annual conference of the National Smoke Abatement Society, which will be held at Liverpool from September 18th to 20th, opens with a reception by the Lord Mayor of that city on the evening of the first day. Papers will be read and discussed on the progress of the electrical grid, and on the production and use in Liverpool of the new smokeless fuel "Dryco." The programme also includes a motor tour, during which visits will be paid to housing estates, the new Clarence Dock power station, and other places of interest. Further particulars about the conference may be obtained from the Society's central offices, 23, King Street, Manchester, up to September 17th, and afterwards at the conference office, Adelphi Hotel, Liverpool.

The Fellowship of Medicine announces special courses in September. At the Hospital for Consumption and Diseases of the Chest, Brompton, the course will last from September 7th to 12th, and will occupy the whole of each day; fee £3 3s. A series of lecture-demonstrations in psychological medicine will take place on Tuesday and Saturday mornings at 11, at Bethlem Royal Hospital, Beckenham, from September 8th to October 3rd; fee £1 1s. A course on diseases in infants will take place at the Infants Hospital, Vincent Square, Westminster, from September 14th to 26th, from 2 p.m. each day; fee £3 3s. Lecture-demonstrations in ophthalmology will be held at the Central London Ophthalmic Hospital, Judd Street, W.C., from September 15th to October 8th; fee £3 3s. At the Westminster Hospital a course in general medicine and surgery, open to men only, will take place from September 14th to 26th, from 10.30 a.m. to 5.30 p.m.; fee £5 5s. for two weeks, or £3 3s. for one week. A course in general medicine and surgery, open to men and women, will be held at the Metropolitan Hospital, Kingsland Road, E., from 10.30 a.m. to 5.30 p.m. from September 28th to October 10th; fee £3 3s., or £2 2s. for either week. Copies of syllabuses of the courses may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

An autumn post-graduate course on diseases of the nervous system will be held at the National Hospital from October 5th to November 27th. The general course will consist of thirty-two clinical lectures and demonstrations at 3.30 p.m. on each weekday except Wednesday and Saturday, teaching in the out-patient department on each weekday except Saturday at 2 p.m., and eight pathological lectures and demonstrations on Friday at 12 noon. The fee for the course will be £6 6s. A course of eight lectures on the anatomy and physiology of the nervous system will be arranged on Tuesdays and Thursdays at 12 noon if there are sufficient applications, fee £2 2s. A course of ten clinical demonstrations, chiefly on methods of examination of the nervous system, will be

ven on Tuesdays and Thursdays at 5 p m , fee £2 2s ickets entitling to attend the out patient clinic only ay be obtained from the secretary , fee £2 2s for ree months Applications should be addressed to the cretary, Medical School, National Hospital, Queen quare, W C 1

A conference on tuberculosis organized by the Davos ledical Society, will be held from October 5th to 10th ectures on the development and course of the pulmonary nd extra pulmonary types and on collapse therapy will e given Those wishing to attend the conference should otify the President of the Society before October 1st, nd those wishing to take part in the discussions before eptember 20th Excursions are being arranged Further etails may be obtained from the secretary, Davos ledical Society, Davos Platz Switzerland

A special post graduate course in the pathology of igestive processes will be held in the Hospital de la anta Cruz at Barcelona from October 23rd until the iddle of December The subjects dealt with will include he examination of gastric juices intestinal secretions, nd faeces , congenital anomalies of the alimentary canal , he diagnosis and treatment of gastric dyspepsia, ulcers, nd malignant growths , the pathology and therapeutics f cirrhosis constipation, and pancreatic disease , applied adiology and disorders of the spleen, liver and appendix herapeutic demonstrations will be given of the various iagnostic and therapeutic procedures employed Further nformation may be obtained from the director of the ospital, Professor F Gallart Mones

The second International Congress on the Rat and Plague will be held in Paris from October 7th to 12th urther information can be obtained from the general ecretary Professor Gabriel Petit, 84 bis, Rue de Picpus, Paris XIIe

The second International Congress of Comparative Pathology will be held in Paris at the Faculty of Medicine rom October 14th to 18th Professor Charles Achard will reside The subjects for discussion include B C G mmunization Brucella infections in man and animals mineral salt deficiencies in man and animals the distribu ion of the ultra virus agencies and the diseases attri outable to them , and helminthic infections The congress s open to medical and veterinary practitioners and those nterested in the diseases of plants Further information may be obtained from the general secretary, 7, Rue Gustave Nadaud, Paris XVI

The King has granted permission to Dr Douglas Erith Derry M C to wear the Insignia of the Second Class of the Order of the Nile conferred upon him by the King of Egypt Dr Salvator Michael Vassallo F R C S has also received licence and authority to wear the Insignia of the Fourth Class of the Order of the Brilliant Star of Zanzibar conferred upon him by the Sultan of Zanzibar The *London Gazette* also announces that the King granted his Royal licence and authority to Dr Theodore Dyke Acland to wear the Insignia of the Second Class of the Order of the Nile conferred upon him by the King of Egypt (Dr Acland died on April 16th last)

Professor W D Halliburton, M D , F R S , who died on May 21st has bequeathed, on the death of his wife £10 000 to King's College University of London, for endowment or towards the salary of a professor in the subject of physiology or the sciences relating thereto He leaves also £300 to his medical attendant ' as a small recompense for his faithful and untiring service "

The lecture on eugenics which Colonel C J Bond, C M G delivered as an introduction to the Sims Woodhead course of lectures last February, under the auspices of the People's League of Health, has now been published in pamphlet form and can be obtained from the offices of the League, 12, Stratford Place London W 1

William Heinemann (Medical Books) Ltd announce for publication this autumn a book by Dr Bendien, entitled *Specific Changes in the Blood Serum*, translated by Dr V Pines

Letters, Notes. and Answers

All communications in regard to editorial business should be addressed to **The EDITOR British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square W C 1 on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Publishing Manager

QUERIES AND ANSWERS

Development of the Ovum of Ascaris lumbricoides

Dr. H. WARBURTON LEWIS (Newbury, Berks) asks what is the time occupied by the development of the ovum of *Ascaris lumbricoides* to the adult worm stage.

*** The ovum of *Ascaris lumbricoides* when passed out in the faeces is in an undeveloped and non-infective condition. At 33° C., the optimum temperature for development, a larva develops in the egg in from nine to thirteen days. It is now infective for man, and may remain so for very considerable periods—certainly well over a year. Infection occurs by swallowing the egg, and the larva which hatches becomes mature in from two to two and a half months. Thus, the minimum time for the complete life-cycle (egg to egg) is about two and a half months. The worm is recognizable as an ascaris, of course, some time before it is mature and laying eggs—probably about a month after the egg has been swallowed.

Income Tax

Replacement of Car

"J. F." has in the past claimed and been allowed a deduction for replacement of his cars equal to the excess of the cost of the car displaced as *at the date of disposal* over the amount actually received for it. The last replacement has worked out as follows: cost of car similar to the one displaced, £310; actual amount received, £175; claim, £135. The car purchased, however, cost £206 only, and the inspector of taxes refuses to allow more than £206 − £175 = £31.

*** The inspector is right. The allowance normally is represented by the amount of the actual out-of-pocket expense, but when the cost of cars is increasing generally, or the new car is better than the old one, the cost of "replacement" is strictly less than the actual expenditure, because the latter includes an element of capital outlay which is not allowable for income tax purposes. As a result, the cost of replacement does not work out as fairly as the "percentage depreciation" allowance, and that is one reason why we have consistently advised practitioners to adopt the latter basis.

LETTERS, NOTES, ETC.

Transmission of Ultra-violet Rays through Fabrics

We have received the following communication from the Experimental Department of the Fine Cotton Spinners' and Doublers' Association, Ltd.:

From time to time, during the last few years, statements have appeared in the press to the effect that artificial silk (rayon) fabrics are more permeable to ultra-violet rays than fabrics made from other textiles. A similar remark made at a recent important medical meeting has again called attention to this subject. The original authority for these statements is not clear, and it is obvious that any pronouncement coming from an interested section of the textile industry on the relative transmission of ultra-violet rays through fabrics should be cautiously accepted. So far as we are aware, the only authoritative information on this subject that has been issued by an impartial body of investigators is the report by Messrs. Coblentz, Stair and Schoffstall, which will be found on page 105, vol. i, 1928, of the United States Department of Commerce *Bureau of Standards Journal of Research*. This report not only records investigations in the relative transmission of ultra-violet rays through linen, cotton, viscose and acetate artificial silk, natural silk, and woollen fabrics, but also the influence of weave, dyeing, bleaching, and discoloration with age on the percentage transmission. To those keenly interested in the subject we advise reading the whole report, but the following excerpt, which is taken from the authors' summary of their work, is sufficiently definite to show that artificial silk cannot claim superiority over other textiles in transmitting ultra-violet rays:

"Fabrics of close-weave and open-weave (twill, satin, voile) material were examined. The results obtained on these different weaves are in agreement in showing that, comparing materials having the same weight, there is practically no difference in the amount of ultra-violet transmitted through bleached samples of cotton, linen, viscose rayon, and the rayon made by the cellulose acetate process. The fresh, white, natural silk is almost as transparent as bleached cotton, while wool is only about half as transparent to ultra-violet solar radiation as bleached cotton. In all cases when the fabric is dyed, or slightly yellowed with age, the ultra-violet transmission through the thread is greatly decreased. Hence, as is to be expected, in comparing various kinds of dyed fabrics, the one having the largest openings between the threads transmits the most ultra-violet."

The important point to note from the above is that it is the structure of the fabric that matters, not the [illegible] textile material of which it is made. The details in the report also show that the percentage transmission of ultra-violet rays through an acetate artificial silk fabric dropped from 20 to 2 as a direct result of colouring with a red [illegible]

Holidays for Factory Girls

We have received the following letter, signed on behalf of the Factory Girls' Country Holiday Fund by the Countess of Sandwich, Mrs. Creighton, J.P., Miss Lilian Brutton, Dr. Octavia Lewin, the Chief Rabbi, Mr. J. L. Stocks, and Mr. J. F. Green: At this time, when "all the world" (as we say) is making holiday, or preparing to do so, we trust that they will spare something for that considerable remainder which cannot afford a holiday, or not on a [illegible] scale. In particular, we ask them to remember once more, as they have in former years, the Factory Girls' Country Holiday Fund. Last year this fund arranged 1,230 weeks of holiday for 1,030 women and girls at a cost, including travelling, of £1,630, of which sum more than one-third was contributed by the holiday-makers themselves. We would call special attention to this last point. Those who give to this fund have assurance, not merely that the money they give will be well spent, but also that they encourage the wise spending of much other money, the hard-earned savings of the girls themselves, so that every pound they give will in effect provide a full week's holiday for a working woman. This is surely a good investment from a strictly financial point of view; and if anyone has other doubts, these can soon be settled by a visit to the quarters during the holiday season. The eager and excited crowds alone will tell him much, and a comparison between the group that is ready to go off and the group that has just come back will tell him the rest. Lastly, the subscriber may be assured that the fund is in the hands of careful and competent administrators, who make every effort to secure that girls are helped only so far as they cannot help themselves, and that they are encouraged throughout the year, by means of saving-cards and in other ways, to make the most of their ability to help themselves. Even in these difficult times we hope that support will be forthcoming generously and promptly for this work. Subscriptions and donations will be thankfully received and acknowledged by the honorary treasurer, Mrs. Slater, or by Miss Canney, 75, Lamb's Conduit Street, London, W.C.1.

A Library of X-Ray Films

Messrs. MASSON ET CIE (120, Boulevard Saint Germain, Paris) have recently published a library of radiographical films which consists of groups of x-ray photographs so reduced in size that a package containing thirty or forty can be carried in the pocket. The dimensions of the package are 9 inches by 2¼ inches. In each of these packets are three and sometimes four, light frames, resembling very much the old-fashioned lantern slide, and by simply placing the frames on a piece of white paper or holding them up to the light, a satisfactory illustration of the pathological condition can be obtained. The frames can also be used as lantern slides. Of the fifty groups, mention may be made of those of the ossification of the periosteum, the radio-diagnostic methods of gynaecology, fractures of the carpus. The cost of each group is 25 francs.

A Warning

A doctor informs us that a man calling himself Kelk and claiming to represent the Thistle Press (457, Liverpool Road, N.7) has been hawking specimens of labels for bottles and bottle wrappings in the Wembley district. Our correspondent made a payment to this man for goods that were not delivered; the Thistle Press states that the man is neither one of its agents nor on its staff. Practitioners are warned to be on their guard if they receive similar visits.

Corrigendum

Owing to a clerical error the word "weeks" was substituted for the word "months" in the fourth line of Dr. Harbord's letter in the *Journal* of August 22nd (p. 367). The letter should read: "after suffering from a painful right hernia rather more than two months."

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 34, 35, 36, 37, 38, 39, and 40 of our advertisement columns, and advertisements of partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 171

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

The Duration of Weight Reduction after Dieting

ıBER (*Ugeskrift. f. Laeger*, July 2nd, 1931, p. 703) :tudied the late results of dietetic treatment for y in the hydropathic establishment, Montebello, ıtients of the well-to-do class in Denmark. Since patients could not be summoned to report them- ; for re-examination as if they belonged to the ary hospital class, only those patients were avail- for this study who returned voluntarily from time ne for renewed treatment. Of the 154 patients who repeated their visits as many as 102 were women, 67.5 per cent. were between the ages of 40 and 60. men were most numerous between the ages of 40 and he women between 50 and 60. With only few ɔtions, these patients suffered from other ailments obesity, but many of these ailments were either :s or sequels of the obesity. The average duration reatment was 35 days. The average loss of weight ıg a course of treatment was 5.6 kilos, being 5.8 for and 5.5 for women. The dietetic treatment was ılemented in many cases by thyreoidin, which was :ribed when a mixed diet with a low total caloric e had failed to bring the weight down satisfactorily. ınalysis of the weights of the patients on re-admission ·ed that only 42 per cent. had derived any durable :ovement from their previous sojourn. The most essful cases in this group were represented by 7 men 37 women, who were found on re-admission to have : the same weight to which they had been reduced discharge, or even to have fallen below this weight. :omparison of the patients who kept their reduced ghts down with those who returned to their former ;ity failed to establish any correlation between the nanency of the results on the one hand and the dura- : of the treatment, or the average loss of weight per , on the other hand. The author suggests that the nces of the results of dietetic institutional treatment ıg maintained indefinitely may be enhanced if the ient is taught in the institution to appreciate a diet ch does not inflict the pangs of hunger, and is not oic to the verge of discomfort.

172 Syphiloderma Pustulosum

THURMON and D. BLAIN (*Amer. Journ. Syph.*, April, ·1, p. 213), who record a personal case, state that ·tu'ar syphiloderma, which was first described in detail Wallace of Dublin in 1835, is an uncommon manifesta- ·n of secondary syphilis. Their case, which occurred a man aged 29, was apparently similar to the form of ılignant syphilis which was common during the epidemic the disease at the close of the fifteenth century. The ılignancy was shown by the rapid development of structive ulceration within a few months of the primary ·ion, by the circular character of the ulcers, their wide ·tribution, and their coexistence with mucous patches ıd cutaneous nodules. Osteomyelitis of the right tibia veloped during the acute stage of the infection, while e patient was receiving moderately intensive treatment the form of intravenous injections of salvarsan or ·osalvarsan and intramuscular injections of mercury ıccinimide. Rapid improvement, however, subsequently ·sued, contrary to what usually occurs in malignant ·philis. On histological examination the cutaneous lcers showed acute and advanced stages of inflammation. he acute inflammatory lesions were characterized by the resence of moderate numbers of polymorphonuclears, ·ith plasma and endothelial cells, thrombosed blood essels, and collagen fibre degeneration, while the more dvanced lesions showed an increased number of plasma nd endothelial cells, fewer polymorphonuclears, ·ccasional giant cells, and more extensive collagen degeneration. Intratesticular inoculation of rabbits with emulsions of the cutaneous ulcers failed to reproduce syphilis, but gave rise to a generalized staphylococcal infection. It is considered possible, however, that the therapeutic injections preceding the biopsy had sterilized the ulcer, or had so much reduced the vitality of any treponemes present as to prevent the reproduction of infection in another animal.

173 Hyperazotaemic Nephritis in Typhoid Fever

J. SABRAZÈS and J. LEVY (*Gaz. Hebd. Sci. Méd. de Bordeaux*, May 31st, 1931, p. 337, and June 7th, 1931, p. 354) who record four illustrative cases in men aged from 19 to 38, state that typhoid fever may be complicated by hyperazotaemic nephritis. In two cases the amount of blood urea exceeded 1 gram, and in one case of anuria 10 grams. All these three cases were fatal. Contrary to the opinion of some writers, especially Roch of Geneva, this high degree of azotaemia is due to renal changes, as is shown by the presence of casts and the post-mortem lesions. The hyperazotaemia does not necessarily give rise to a low temperature, nor is it always accompanied by a considerable fall in the excretion of urea in the urine. The onset is insidious; vomiting among other signs is suggestive. In one of the present authors' cases in which the hyperazotaemia exceeded 6 grams recovery ensued, and was attributed in part to a liquid diet poor in nitrogen, subcutaneous injections of an isotonic solution of glucose in doses of 500 c.cm. daily, subcutaneous injections of oxygen, and to washing out the stomach.

Surgery

174 Treatment of Bladder Diverticula

R. LE FUR (*Bull. et Mém. Soc. Chir. de Paris*, June 19th, 1931, p. 414) points out that, owing to the grave surgical risk, the removal of diverticula of the bladder is seldom advisable, and recommends a different method of treatment, particularly for posterior and lateral diverticula. This consists of the permanent drainage of the diverticulum, with evacuation and direct disinfection by means of large urethral or Pezzer-Le Fur sounds, which are introduced directly into the cavity of the diverticulum. Through these lavage can be arranged five or six times a day, with protargol, silver nitrate, collargol, or lipiodol. Even in cases where the removal of the diverticulum is a necessity, preliminary drainage and disinfection lessens the operative risk by reducing the danger of infection. Prostatectomy, in cases of operable adenoma, frequently causes the diverticulum to diminish in size or even to atrophy completely. Antero-superior diverticula of congenital origin, which are usually very large, should not be removed, but should be treated by marsupialization of the diverticulum to the abdomen. A case is quoted in which this procedure was undertaken after the removal of a large calculus from a bladder diverticulum. It was found that the diverticulum atrophied after continued disinfection with silver nitrate, and deep cauterization by high-frequency current of the fistula which resulted. The cystostomy was then closed, and the patient made a good recovery.

175 Course and Treatment of Ruptured Hydatid Cysts

B. PERICIC (*Wien klin. Woch.*, June 5th, 1931, p. 735, and June 12th, 1931, p. 770) reports 57 cases of ruptured hydatid cysts, and arranges them into the following groups. (1) Hydatid of lung perforating into bronchus or pleura (20 cases) has, according to the author, the most favourable prognosis, the great majority of the patients recovering without operation. Surgical treatment should only be considered in the case of complications such as pyothorax.

(2) Hydatid cysts of liver perforating into the bronchus or pleura (8 cases) are not so favourable. An operation is generally indicated, and the approach may be transpleural or peritoneal. In this group it is, of course, better to operate before perforation has occurred. (3) Hydatid of liver perforating into the alimentary canal (7 cases) is usually marked by diarrhoea, with passage of membranes and sudden diminution of the hepatic tumour. An operation is only necessary in cases of complications such as subphrenic abscess, and recovery is the rule. (4) Hydatid of the liver perforating into the bile passages (3 cases) is marked by severe jaundice, and many patients die from suppurative cholangitis. An early operation is indicated. (5) Perforation into the urinary tract (3 cases) is usually favourable in its course, and operations are only undertaken for pain or obstruction. (6) Perforation into the peritoneal cavity (9 cases) is again a serious condition; the diagnosis is difficult, and an operation is usually necessary. (7) Perforation through the skin (6 cases) involves incision and drainage usually, but good results ensue. In one case of perforation into the bronchus it was uncertain whether the primary site of infection was in the liver or the lung. A short history of each case recorded is supplied by the author.

176 Aneurysm of the Pulmonary Artery

Despite their rarity as compared with aortic aneurysms, aneurysms of the pulmonary artery occur with sufficient frequency to require consideration in the differential diagnosis of mediastinal tumours. H. R. Wahl and R. L. Gard (*Surg., Gynecol., and Obstet.*, June, 1931, p. 1129) report a typical case of this type in which the aneurysm, having been diagnosed as a solid mediastinal mass, was opened with resulting fatal haemorrhage. A brief summary of fourteen cases reported in the literature is also given. The clinical diagnosis of pulmonary aneurysm is very difficult; according to Henschen, the diagnosis can be made when seven signs, here enumerated, are simultaneously present. The etiology is not yet definitely established, but sex is apparently of little significance; age is seemingly of greater import, since the majority of cases occur in patients under the age of 30, this being in distinct contrast with aortic aneurysms. Endo- and peri-carditis are probably unrelated, and secondary rather than causal. Pulmonary aneurysms are usually associated with some congenital cardiac malformation, and often have a syphilitic base. In the present case, though there was no history or signs of syphilis, the histology of the pulmonary trunk wall, of the smaller pulmonary branches, and of the aneurysm was exactly comparable with that seen in syphilitic arteritis and aortitis.

177 Oesophageal Carcinoma

D. H. and A. N. Bessesen (*Amer. Journ. Surg.*, June, 1931, p. 437) point out the great difficulty of successful operative treatment in cases of carcinoma of the thoracic oesophagus, but without operation for the complete removal of the growth the mortality is 100 per cent. Carcinoma of the oesophagus is highly malignant, and the patients are always in poor condition, necessitating prolonged preoperative care and a special diet of protein, fats, carbohydrates, iron, and vitamins. Surgical difficulties include the inaccessibility of the organ, its anatomical relations and structure, the absence of a serous coat, and the poor blood supply; these account for the frequency of necrosis, and the danger of post-operative infections of the neck, mediastinum, pleura, and lung. The technique of what the authors consider the ideal operative procedure is described. As a preliminary operation, a Janeway or Witzel gastrostomy is performed under local anaesthesia, and the liver and lymphatics in the region of the diaphragmatic oesophagus are inspected. Two to six weeks are then allowed for recovery before artificial pneumothorax is induced; the thorax is opened under necrosis and local anaesthesia. The pleura must be protected with rubber sheets; the oesophagus is dissected from its mediastinal bed, and drawn out through the neck, care being taken to control haemostasis and protect the vagus nerves. The carcinoma must be completely removed, and finally the air must be removed from the thorax, the chest being then tightly strapped. Healing is allowed to continue for seven days before the stump in the neck is opened, after which the patient is permitted to drink, and to wash the oesophagus through with fluids. A case is reported in which the patient was in excellent condition forty-eight hours after the operation, but suddenly collapsed and died on the third day. The operation is described as a heroic measure; in most cases patients who survive the operation do not live more than about fifteen months, death being due to recurrence and not to metastases. Since death from this disease is certain, however, without operation, surgical removal of the growth should be attempted in every case where there is no evidence of metastasis.

Therapeutics

178 The Administration of Vegetable Vitamins

S. Warren and H. A. Nissen (*New England Journ. of Med.*, July 16th, 1931, p. 135) have devised a comparatively simple apparatus for preparing a vegetable extract with a high vitamin content. Ordinary methods of vegetable cookery are wasteful and leave an indigestible cellulose residue of small nutritive value with hardly any vitamin or mineral content. Vegetables are usually boiled at a temperature sufficient to destroy vitamin activity, and the bulk of their soluble nutrient content is poured away. Cooking them without water necessitates unremitting attention; although the mineral salts are retained, the vitamins are destroyed and the amount of cellulose remaining is excessive. The ideal vegetable food should have a low cellulose content, retain all its vitamins and salts, and contain glucose. The authors' extract is made as follows. After thorough cleansing, all leafy vegetables are sliced or ground; roots are shredded. This pulp is then mixed with a quantity of dilute orange juice and placed in the colander of a ten-gallon steam-jacketed aluminium kettle, the temperature of which is controlled by regulating the admission of steam to the jacket. A steam-driven rotary pump circulates hot water and secures percolation. A cover (removable for stirring) maintains an even temperature. After three-quarters of an hour, the vegetable juice is drawn off into sterilized bottles, which are stored in a refrigerator; fermentation may occur otherwise, and the fluid cannot be sterilized without destroying the vitamins. Patients usually prefer carrot juice; spinach, beet, and cabbage were found to be palatable in the order named. Celery juice thus prepared is too strongly flavoured, except for use in soups. These juices may be given undiluted, or in milk or soup, before boiling temperature. If a known weight of "roughage" is desired, this can be added to the soup from the cellulose residue. Animal experiments showed the high vitamin content of these juices. Since ordinary dietaries are deficient in vitamins and salts, a liquid preparation that can be diluted, added to soups, or mixed with cereals, is obviously valuable in hospitals and elsewhere.

179 Treatment of Chorea by Nirvanol

According to F. Goebel (*Deut. med. Woch.*, July 31st, 1931, p. 1313), nirvanol (phenyl-ethyl-hydantoin) is the most powerful and certain remedy at present in use against chorea; not only is the disease usually controlled or cured by its administration, but endocarditis is said to be especially rare in such cases. On the other hand, it is known to cause severe symptoms; but since the treatment is often unsuccessful unless some of these symptoms appear, they are apparently unavoidable. Nirvanol may damage the haematopoietic system, giving rise to a picture of agranulocytic anaemia or purpura. Nephritis may occur, and the exanthem associated with this drug may run a malignant course suggestive of exfoliative dermatitis. Any of these ill effects may prove dangerous, and the author now only uses this line of treatment when all other remedies have failed and the dangers have been explained to the patient or his relatives.

) Intravenous Vaccination with Haemolytic Streptococci

G. WILSON and H. F. SWIFT (*Amer. Journ. Dis. d.*, July, 1931, p. 42) have attempted to desensitize oup of children susceptible to rheumatic fever with nolytic streptococcal vaccine. The present investiga- covers a four-year period of observation, from 1927 930, during which 172 children were selected for study, majority being under 10 years old. Approximately half of the children received intravenous vaccination, the remainder, a comparable group, served as controls. vaccine was prepared from a strain isolated from tonsillar exudates of a patient who had suffered for ıths from severe polyarthritis and carditis. The first ction consisted of 250,000 micro-organisms, and each sequent weekly injection contained double that of the ceding one until the maximum of 10,000,000 was reached; ; dose was repeated until a total of from nine to twelve ıtments had been given. Fifty children received a ond course of treatment. Twenty patients with active ease were treated—fifteen suffering from chorea and : with active carditis. General reactions, such as rexia and headache, were infrequent and slight, and al reactions were not observed. No untoward sym- ms developed in any child, and 45 per cent. of the ated children, as compared with 18 per cent. of the ıtrols, were free from recurrence for periods of sixteen nths to two years after treatment. The authors think probable that the intravenous vaccination bears some ationship to the diminished incidence of recurrence served, though the relatively few numbers and short iod of observation preclude any very definite con- sions. It was not clear whether there had been specific munization with the haemolytic streptococci, or a non- cific protein irritation, and the data presented do not licate whether yearly courses of such treatment are visable.

Laryngology and Otology

181 Lateral Adenoid Vegetations in the Adult

. JACOD (*Ann. d'Oto-Laryngol.*, April, 1931, p. 399) ıws attention to the well-known clinical observation ıt the lymphatic tissue of the fossa of Rosenmüller ten undergoes important pathological change in adults, en in those patients who have shown no signs of enoids in infancy or childhood. These lateral adenoid getations are subject to attacks of acute inflammation, e condition becoming chronic eventually, with retention caseous material. The process tends to spread to the ıstachian tubes, and, if untreated, produces deformity d stricture. Patients with this condition are often bject to recurrent otorrhoea. Other symptoms are minution of hearing, tinnitus, and shooting pains below e lobule of the ear. Great amelioration of symptoms obtained by squeezing out the inflammatory exudate d caseous material from the adenoid growths. Having ade his diagnosis in such cases Jacod expresses the secre- ın from any vegetations present by palpation of the sopharynx with the index finger. He states that this n be accomplished with very little discomfort to the tient if a little cocaine is placed in the nasal fossae, id the head is inclined to each shoulder in turn. It is aimed that in those cases where Eustachian catheteriza- on produces improvement of a short duration only, the fect is rendered more lasting if the nasopharynx is first eated in the way previously outlined.

182 Tuberculosis of the Middle Ear

rCLAIR THOMSON (*Journ. of Laryngol. and Otol.*, July, 931, p. 460) discusses his findings from examining the ıral condition of all tuberculous patients admitted to ing Edward VII Sanatorium, Midhurst, since 1911. e believes that tuberculosis of the middle ear is a mparatively rare complication in pulmonary disease, curring in less than 2 per cent. of the cases admitted to a sanatorium. The painless onset of a scanty and thick otorrhoea, with marked deafness, in an adult, is suggestive of a tuberculous origin, but only in a minority of cases can the bacilli be found in the oral discharge. This form of otitis media occasionally heals under sanatorium treatment, and active local measures are rarely required. The complication indicates a severe infection, and its discovery justifies a grave prognosis, since the infection is very severe, or the patient's resistance is low. F. C. ORMEROD (ibid., p. 449) discussing this condition, agrees that it is uncommon, or, at any rate, not frequently diagnosed with certainty. The possible pathways of infection are the Eustachian tube and the blood stream, the external auditory meatus being very rarely concerned. Multiple perforations of the drum are usually seen; they may heal or enlarge and finally coalesce. In children there is a pronounced tendency in this condition to mastoid involvement; facial paralysis, due to pressure from granulation tissue, is much more common. Aural tuberculosis in young children is more active than in adults, and there is a greatly enhanced liability to involvement of other parts of the temporal bone and infection of the meninges.

183 Results of the Radical Operation for Otitis Media

J. JESSEN (*Ugeskrift f. Laeger*, April 30th, 1931, p. 470) reports a study of 341 cases of middle-ear disease operated on between 1923 and 1926; 30 patients died in hospital, and 3 died later of diseases unconnected with the ear. Of the remaining 308 patients 107 did not present themselves for re-examination, and 3 were operated on afresh elsewhere. Thus there remained 198 patients (68 men, 73 women, and 57 children) of whom 7 were operated on on both sides, the total number of ears being, therefore, 205. As to the question whether the operation does or does not protect the patient from subsequent dangerous endocranial complications, it was significant that they had not occurred in even one of the cases followed up. But while 102 patients had no discharge after the operation, there were as many as 103 who still had a purulent discharge. Jessen points out that functional improvement after the operation varies greatly in the statistics of different operators, and concludes that the more conservative the surgeon is in his indications for the radical operation the lower will be his percentage of successes. In an analysis of 100 carefully re-examined patients he found that among 52 patients in whom a good operative result could be claimed, there were as many as 43 whose general condition was good. Among the 35 in whom only a moderately satisfactory operative result was achieved, there were only 21 whose general condition was good; and among the 13 with a poor operative result, there were only 4 with good general health.

Obstetrics and Gynaecology

184 Sodium Amytal as an Analgesic in Labour

E. C. HAMBLEN and D. O. HAMBLIN (*Amer. Journ. of Obstet. and Gynecol.*, May, 1931, p. 715) in a preliminary report describe the results of the oral administration of sodium amytal (sodium iso-amylethyl-barbiturate) in fifty patients with regular pains in the commencement of the second stage of labour. This drug, described in 1926, has been used as an anaesthetic by several American observers, and is usually given intravenously. In obstetrics an initial dose of 15 to 18 grains, with not more than two additional doses of 6 grains, is recommended. About half an hour after the first dose the patient becomes drowsy, and sleeps between the pains, but restlessness and excitement during delivery are not uncommon, and call for the administration of nitrous oxide. With the recommended doses amnesia was perfect in twelve out of fourteen primiparae, and in ten out of nineteen multiparae. Variations in susceptibility occur, and there may be idiosyncrasy, careful supervision and regular readings of the blood pressure are necessary. One patient with pregnancy toxaemia had vasomotor collapse requiring treatment by intravenous infusion and ephedrin.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

SUPPLIED in WIDTHS

2"	2½"	3"	
1/7	1/9	2/-	EACH

When stretched measure six yards (approximately).

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS.

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel: 64117 *For terms, etc., apply to the Medical Superintendent*

President LORD WAKEFIELD OF HYTHE, C B E, LL D.
Treasurer SIR LIONEL LAUDEL PHILLIPS, Bart.
Physician Supt J G PORTER PHILLIPS, M D, F R C P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition
With a view to early treatment voluntary or uncertified patients are admitted
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical Pathological and Psychological Laboratories
Furthermore, provision is made for Electro-Therapy and Hydro Therapy to be carried out in all their forms
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms
For forms and further particulars apply to the Physician Superintendent at the Hospital

Safeguarding the Purchaser.

Although Advertising has become an integral part of modern business, its advantages to the consumer are not always clearly realised A little thought will show, however, that any product marketed under a recognised name or trade mark must reach a high standard of quality, for were this not so "repeat sales" could not be secured, recognition of a discredited brand reacting to the disadvantage of the manufacturer in inverse proportion to the benefits that are derived when a large and satisfied clientele see, in the name of the product, a guarantee of quality and efficiency

This argument leads one to expect that branded goods will represent better value than others, and that the standard will be maintained

Advertising further benefits the purchaser by making possible reductions in the selling price consequent upon increased production resulting from the larger demand created by the advertising campaign The manufacturer of advertised goods places his cards upon the table, supplying information concerning the product which enables the prospective purchaser to form a judgment upon its suitability to his own particular needs, whereas non advertised goods rely entirely upon recommendations, often of a confused nature, and it is left to the purchaser to find at his own cost the real value of the product.

It is safe, therefore, to assume that in the majority of cases advertised goods only should be purchased The advertisement pages of the *Journal* contain offers of a variety of goods and of service designed to meet the professional and personal needs of the medical man.

It should be remembered that while the acceptance of advertisements for publication in the *Journal* is not to be understood to imply a recommendation or guarantee, and while no responsibility can be accepted with regard to the accuracy of the statements contained in advertisements, a very strict censorship is maintained by the Journal Committee, and every effort is made to ensure that the claims set forth are well founded In this way a degree of confidence has been established between readers and advertisers in the *British Medical Journal* which cannot be paralleled by any similar publication in the British Empire.

The Triumph of Cow & Gate

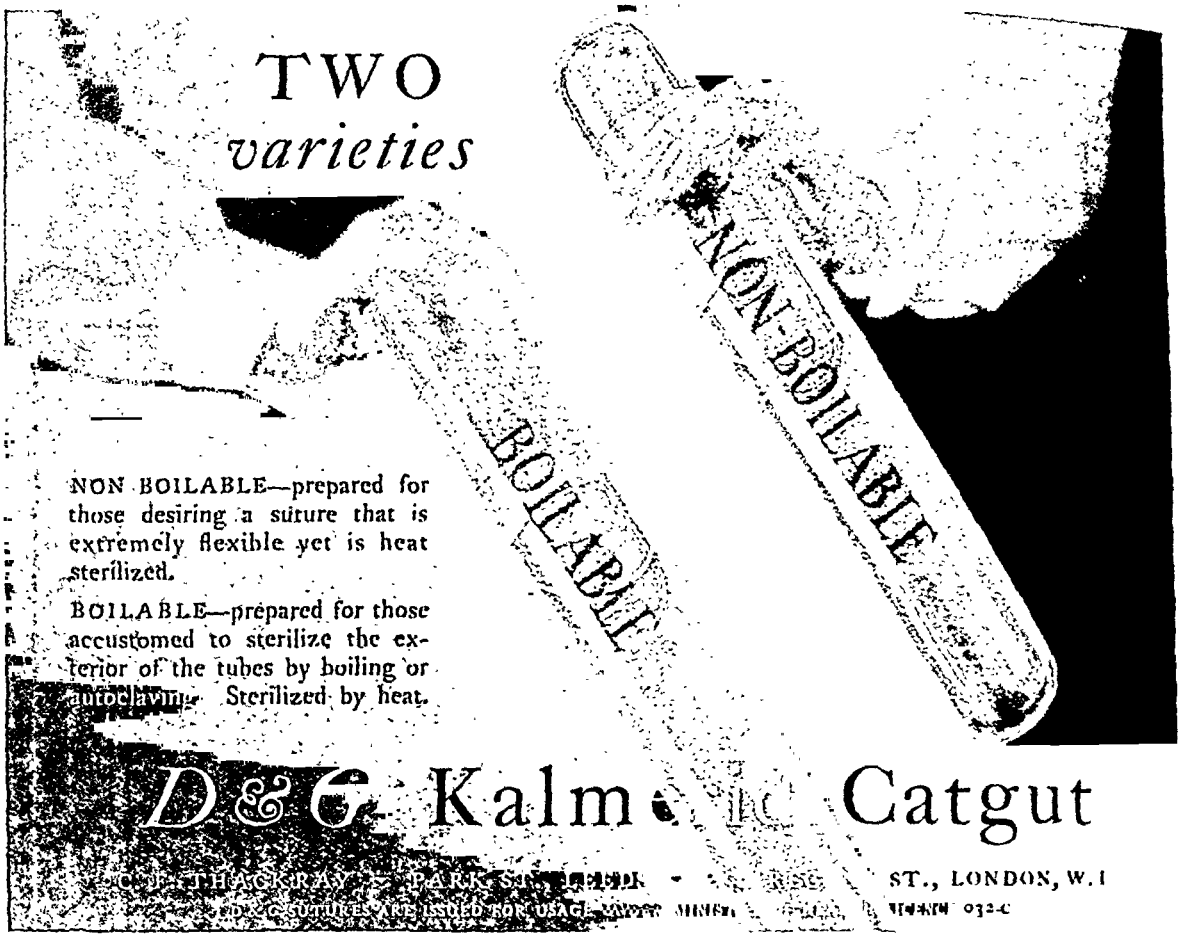
LET the microscope show you the extraordinary similarity between Cow & Gate Milk Food and Breast Milk in a baby's stomach. Note also that ordinary milk powder—that is not prepared by our Improved Roller Process—is no better than raw cow's milk. Raw cow's milk is no food for human babies. Nature intended it for the calf!

COW & GATE — BREAST MILK — RAW COW'S MILK — ORDINARY MILK POWDER

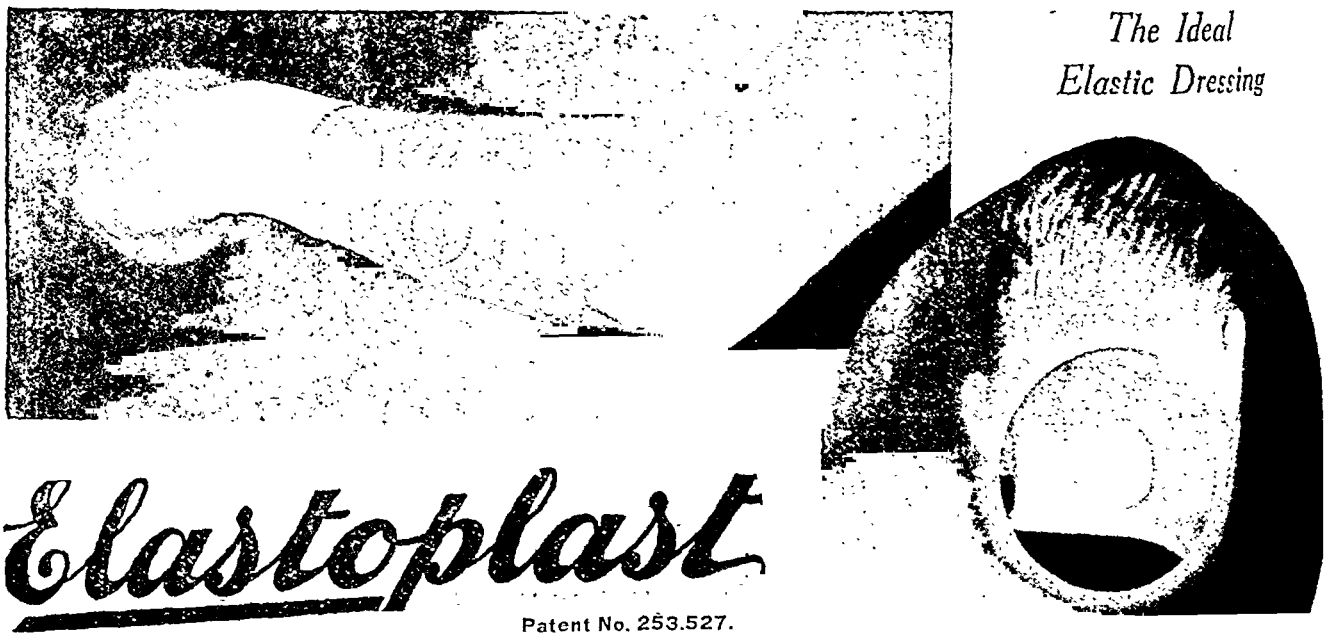
"Next best to Breast" — *"Hard and Indigestible"*

Support our Farmers at home—there is no imported milk in Cow & Gate

Some Babies cannot digest rich milk; put them on Cow & Gate Half Cream . . . 2/6 (BLUE TIN)



Cow & Gate Milk Food



"Cow's Milk made Safe and Suitable for Baby"

Export Cow & Gate especially packed for Hot Climates (YELLOW TIN)

J. & A. CHURCHILL

ROGERS & MEGAW'S TROPICAL MEDICINE

By Sir LEONARD ROGERS, C.I.E., F.R.S., and Maj.-Gen. J. W. D. MEGAW, I.M.S., C.I.E.
1 Coloured Plate, 77 Text figs. 14s. Postage 9d.

14th Ed. 64 Plates, 12 Coloured, and 103 Text figures. 25s. Postage 1s.

25s. TAYLOR & POULTON'S PRACTICE OF MEDICINE 25s.

Edited by E. P. POULTON, with the Assistance of C. P. SYMONDS, H. W. BARBER, and R. D. GILLESPIE

"The cost of this valuable book has been actually reduced. The amount of work must have been enormous, and the result is certainly most successful."—BRITISH MEDICAL JOURNAL.

DUKE-ELDER'S PRACTICE OF REFRACTION
208 Illustrations. 12s. 6d. Postage 6d.

PINEY'S DISEASES OF THE BLOOD
20 Illustrations, 6 in colour. 12s. 6d. Postage 6d.

PINEY & WYARD'S ATLAS OF BLOOD DISEASES
36 Illustrations, 32 Coloured. 12s. 6d. Postage 5d.

ROMANIS & MITCHINER'S SURGICAL EMERGENCIES
158 Illustrations. 13s. Postage 9d.

SYDNEY SMITH'S FORENSIC MEDICINE
3rd Ed. 170 Illustrations. 24s. Postage 9d.

MOORE'S MEDICAL OPHTHALMOLOGY
2nd Ed. 8 Plates. 92 Illustrations. 18s. Postage 9d.

CAMERON'S TEXTBOOK OF BIOCHEMISTRY
2nd Ed. 2 Plates and 12 Illustrations. 15s. Postage 9d.

CAMERON & WHITE'S PRACTICAL BIOCHEMISTRY
4 Plates, 23 Text figures. 8s. 6d. Postage 6d.

GOLDZIEHER'S THE ADRENALS—PHYSIOLOGY, PATHOLOGY, AND DISEASES
73 Illustrations. 30s. Postage 9d.

FALTA'S ENDOCRINE DISEASES
3rd Ed. 104 Illus. 36s. Postage 1s.

GOULDEN'S REFRACTION OF THE EYE
180 Illustrations. 10s. 6d. Postage 6d.

CHEMICAL METHODS IN CLINICAL MEDICINE
By G. A. HARRISON, M.D. 2 Col. Plates. 63 Text figures. 18s. Postage 9d.

NEAME & WILLIAMSON-NOBLE'S OPHTHALMOLOGY
12 Plates and 194 Figures. 12s. 6d. Postage 9d.

PANTON & MARRACK'S CLINICAL PATHOLOGY
2nd Ed. 12 Plates, 10 in Colour, and 51 Figures. 15s. Postage 9d.

MATTHES' DIFFERENTIAL DIAGNOSIS
Translated with Extensive Additions by I. W. HELD, M.D., and M. H. GROSS, M.D. 4th Ed. 176 Illus. 42s. Postage 1s.

6 Col. Plates. 21 Text figures. 21s. Postage 9d.

LABORATORY DIAGNOSIS—CLINICAL APPLICATION

By I. G. OSGOOD, M.D., Director of Laboratories, University of Oregon, and H. D. HASKINS, M.D., Professor of Biochemistry, School of Medicine, University of Oregon

CONTENTS:—Kidney, Urinary Tract, Nephritis, Diabetes, Pregnancy, Central Nervous System, Gastro-Intestinal, Ductless Glands, Thyroid, Haematology, Respiration, Heart, Laboratory Methods.

PARSONS' DISEASES OF THE EYE
6th Ed. 21 Plates. 348 Illustrations. 18s. Postage 9d.

WILLIAMS' MINOR SURGERY AND BANDAGING
20th Ed. 252 Illustrations. 10s. 6d. Postage 5d.

TOTTENHAM'S HANDBOOK OF MIDWIFERY
102 Illustrations. 10s. 6d. Postage 6d.

JELLETT'S SHORT PRACTICE OF MIDWIFERY
10th Ed. 283 Illustrations. 3 Coloured Plates. 18s. Post 9d.

JELLETT & TOTTENHAM'S GYNAECOLOGY
6th Ed. 364 Illustrations. 21s. Postage 9d.

HALE-WHITE'S MATERIA MEDICA
20th Ed. By A. H. DOUTHWAITE, M.D. 10s. 6d. Postage 5d.

COW'S SYNOPSIS OF PHARMACOLOGY
Revised by G. NORMAN MYERS, M.D., B.S., M.Sc. 2nd Ed. 15 Illus. 7s. 6d. Postage 3d.

BERTWISTLE'S SURGICAL RADIOLOGY
24 Illustrations. 8s. 6d. Postage 6d.

BURNS' INTRODUCTION TO BIOPHYSICS
2nd Ed. 116 Illustrations. 25s. Postage 9d.

JOHNSTON'S SYNOPSIS OF REGIONAL ANATOMY
2nd Ed. 11 Illustrations. 12s. 6d. Postage 6d.

EDEN & HOLLAND'S MIDWIFERY
7th Ed. 9 Plates. 389 Figs. 21s. Postage 9d.

EDEN & LOCKYER'S GYNAECOLOGY
3rd Ed. 32 Col. Plates. 555 Text figs. 36s. Postage 1s.

DARLING'S SURGICAL NURSING
3rd Ed. 149 Illustrations. 8s. 6d. Postage 6d.

DARLING'S ELEMENTARY HYGIENE FOR NURSES
4th Ed. 54 Illustrations. 5s. Postage 4d.

LUCAS'S BOOK OF PRESCRIPTIONS. With an Index of Diseases and Remedies.
11th Ed. 10s. 6d. Postage 4d.

STEVENS & LUCAS' FIRST LINES IN DISPENSING
3rd Ed. 95 Illus. 7s. 6d. Postage 6d.

CLARK'S APPLIED PHARMACOLOGY
3rd Ed. 65 Illustrations. 15s. Postage 9d.

JAMESON & PARKINSON'S SYNOPSIS OF HYGIENE
3rd Ed. 20 Illustrations. 18s. Postage 9d.

THE OPERATIONS OF SURGERY

By R. P. ROWLANDS and J. P. TURNER, Surgeons, Guy's Hospital
7th Edition. 900 Illustrations, 43 in Colour. Two Volumes. 70s. Postage 1s. 3d.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

J. & A. CHURCHILL

5th Edition. 543 Illustrations, 9 in Colour. 21s. Postage 9d.

STARLING'S PRINCIPLES OF HUMAN PHYSIOLOGY

Edited by C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S.

THREE EDITIONS IN THREE YEARS

THE SCIENCE AND PRACTICE OF SURGERY

By W. H. C. ROMANIS, F.R.C.S., and P. H. MITCHINER, F.R.C.S., Surgeons, St. Thomas's Hospital.
Third Edition. Two Volumes. 716 Illustrations. 28s. Postage 1s. 3d.

BOWLBY, ANDREWES AND KEYNES' SURGICAL PATHOLOGY 8th Ed. 224 Illus. 21s. Postage 9d.

MAYNEORD'S THE PHYSICS OF X-RAY THERAPY
106 Illus. 10s. 6d. Postage 6d.

CADE'S RADIUM TREATMENT OF CANCER
13 Coloured Plates and 49 Text-figures. 15s. Postage 9d.

TAYLOR'S MEDICAL JURISPRUDENCE
8th Ed. Edited by SYDNEY SMITH, M.D., D.P.H. With the help of W. G. H. COOK, LL.D. Two Volumes. 49 Illus. £3 3s.

AUTENRIETH'S DETECTION OF POISONS
By WILLIAM H. WARREN, Ph.D. 6th Ed. 60 Illus. 30s. Postage 1s.

LEE'S MICROTOMIST'S VADE-MECUM
Edited by J. BRONTË GATENBY, D.Sc., F.R.M.S., and E. V. COWDRY, M.A., Ph.D. 9th Ed. 9 Illus. 30s. Postage 9d.

HOLDER'S HISTOL. TECHNIQUE, ANIMAL AND PLANT TISSUES By J. T. HOLDER, F.R.M.S. Illustrated.

LUCAS'S MODERN PRACTICE OF PEDIATRICS
By WILLIAM PALMER LUCAS, M.D., LL.D., Professor of Pediatrics, University of California Medical School. 126 Illus. 30s.

SMALL'S TEXT-BOOK OF BOTANY
2nd Ed. With over 1,350 Illus. 21s. Postage 9d.

SMALL'S PRACTICAL BOTANY
Illustrated.

MASSIE'S SURGICAL ANATOMY
121 Illustrations, many in Colour. 15s. Postage 9d.

MASSEY'S PRACTICAL ELECTROTHERAPEUTICS
157 Illus. 21s. Postage 9d.

SEQUEIRA'S DISEASES OF THE SKIN
4th Ed. 56 Coloured Plates. 309 Text-figures. £2 2s.

SIR FRANK CONNOR'S SURGERY IN THE TROPICS
99 Illus. 12s. 6d. Postage 6d.

GIMLETTE'S MALAY POISONS AND CHARM CURES
3rd Ed. 10s. 6d. Postage 6d.

FOWWEATHER'S CLINICAL CHEMICAL PATHOLOGY
Foreword by LORD MOYNIHAN, K.C.M.G. 18 Illus. 8s. 6d. Postage 6d.

THE QUEEN CHARLOTTE'S OBSTETRICS
2nd Edition. 4 Col. Plates. 274 Figs. 18s. Postage 9d.

LAWRENCE'S DIABETIC LIFE
Its Control by Diet and Insulin. A Guide for Practitioners and Patients. 6th Ed. 14 Illus. 8s. 6d. Postage 5d.

YORKE AND MAPLESTONE'S NEMATODE PARASITES OF VERTEBRATES
With 307 Illustrations. 36s. Postage 9d.

LITTLEJOHN'S FORENSIC MEDICINE. Illustrated by Photographs and Descriptive Cases
183 Illustrations. 15s. Postage 9d.

JELLETT'S PRACTICE OF GYNAECOLOGY
5th Ed. 417 Illustrations. 15 Col. Plates. 25s. Postage 9d.

GWATHMEY'S ANAESTHESIA
2nd Ed. 273 Illustrations. 25s. Postage 9d.

HEWLETT'S MANUAL OF BACTERIOLOGY
8th Ed. 38 Plates, 63 Text-figures. 18s. Postage 9d.

Ninth Edition. 73 Illustrations. 24s. Postage 9d.

CUSHNY'S PHARMACOLOGY AND THERAPEUTICS

By C. W. EDMUNDS, M.D., and J. A. GUNN, M.D., D.Sc.

HUMAN PHYSIOLOGY

By F. R. WINTON, M.D., Lecturer on Physiology, Univ. Coll., London, and L. E. BAYLISS, Ph.D., Assist. in Physiology, Univ. Coll., London.
227 Illus. 15s. Postage 9d.

The Recent Advances Series

12s. 6d. each, except Children, Chemotherapy, Surgery, and Analytical Chemistry, 15s. each

CHEMOTHERAPY
G. M. FINDLAY, M.D. 4 Plates. 11 Figs.

PULMONARY TUBERCULOSIS
L. S. T. BURRELL, M.D. 2nd Ed. 32 Plates. 17 Figs.

PSYCHIATRY
H. DEVINE, O.B.E., M.D. Illustrated.

BACTERIOLOGY
J. HENRY DIBLE, M.B., Ch.B. 22 Illus.

MEDICINE
G. E. BEAUMONT, D.M., F.R.C.P., and E. C. DODDS, M.D., M.R.C.P. 6th Ed. 51 Illus.

OPHTHALMOLOGY
W. STEWART DUKE-ELDER, D.Sc., M.D., F.R.C.S. 2nd Ed. 4 Col. Pl. 110 Figs.

ANALYTICAL CHEMISTRY
Edited by C. A. MITCHELL, D.Sc., M.A., F.I.C. Vol. I. ORGANIC. 6 Plates. 19 Text-figs. Vol. II. INORGANIC. 26 Illus.

DISEASES OF CHILDREN
W. J. PEARSON, and W. G. WYLLIE. 2nd Ed. 20 Plates and 34 Figs.

BIOCHEMISTRY

New (11th) Edition

HOWELL'S

New (11th) Edition

Text-book of Physiology

"A large number of excellent text-books by leading authorities have been published the W. B. Saunders Company, but of them all Howell's Physiology might justly be awarded pride of place. It is an old and trusted friend, and has now reached its eleventh edition. During the recent years the advances in physiology, and especially in biochemistry, have been so tremendous that it is now a herculean task to keep even a well-established text-book up to date. For this reason most of the big physiology books have adopted dual or multiple authorship... But Professor Howell still keeps his book to himself, losing nothing, but gaining a great deal in doing so. This is a complete, well-balanced and modern text-book, and is the most readable physiology manual that we know."—IRISH JOURNAL OF MEDICAL SCIENCE.

By WILLIAM H HOWELL Ph D, M D, Professor of Physiology in the Johns Hopkins University. Octavo of 1,039 pages, illustrated. Cloth, 30s net.

Maximow's Text-Book of Histology

"The book is one which can be recommended with confidence as a general work of reference for the more advanced student of this branch of study."—BRIT MED JOUR

By ALEXANDER A MAXIMOW, late Professor of Anatomy, University of Chicago Completed and edited by WILLIAM BLOOM, Assistant Professor of Anatomy, University of Chicago Large octavo of 833 pages, with 604 illustrations, some in colours Cloth, 40s net

Herrick's Introduction to Neurology

"One of the most interesting books of its kind, and is easy to read because of the association of anatomy with development and function in a very attractive way."—IRISH JOUR OF MED SCIENCE

By C JUDSON HERRICK, Ph D, Professor of Neurology in the University of Chicago 12mo of 417 pages, illustrated New (Fifth) Edition Just Issued Cloth, 12s 6d net

Graves' Gynaecology

"Has emanated from the Harvard School of Medicine from the pen, and as regards the illustrations in greater part also from the brush, of the professor of gynaecology. Both Professor Graves himself and the school are to be heartily congratulated on an achievement which is well worthy of the best traditions of its historic birthplace."—BRITISH MEDICAL JOURNAL.

By WILLIAM P GRAVES, M D, Professor of Gynaecology, Harvard Medical School Octavo of 1,016 pages, with 582 original illustrations, 128 in colours Fourth, Revised, Edition. Cloth, 48s net.

Griffith & Mitchell's Diseases of Children

"This book should be of the greatest assistance to post-graduate students, to whom its value will be greatly increased by the comprehensive and well chosen list of references to original papers."—LANCET

By J P CROZER GRIFFITH, M D, Professor of Pediatrics, University of Pennsylvania, and A GRAEME MITCHELL, M D Professor of Pediatrics, University of Cincinnati Two octavo volumes totalling 1,500 pages, illustrated Second Edition, thoroughly revised Cloth, 90s net

Todd & Sanford's Clinical Diagnosis

"A book which is of particular value to the student for the number and the excellence of the illustrations the clarity of the type, and the short but concise notes on the indications for the applications of various tests and the interpretation of the results."—LANCET

By JAMES CAMPBELL TODD, M D, University of Colorado, and ARTHUR HAWLEY SANFORD, M D, University of Minnesota (The Mayo Foundation) Octavo of 765 pages, with 500 illustrations, 51 in colours New (Seventh) Edition Just Issued Cloth, 28s net.

De Lee's Principles & Practice of Obstetrics

"The author may be again congratulated on what is truly a monumental work. The term text-book is inadequate except perhaps would be a more apt description."—BRIT MED JOUR

By JOSEPH B De LEE, A M, M D, Professor of Obstetrics at the Northwestern University Medical School, Chicago Large octavo, 1,140 pages, with 1,128 illustrations on 923 figures, 201 of them in colours Fifth Edition. Cloth, 55s net.

Da Costa's Modern Surgery

"Wide and discriminating reading, evincing the most ample knowledge of the literature of his subject, a scrupulous fairness in appraising other men's ideas and methods, a transparent honesty, and complete absence of dogmatism, are the most attractive features of this book."—DUBLIN JOURNAL OF MEDICAL SCIENCE

By J. CHALMERS DA COSTA, M D, Professor of Surgery, Jefferson Medical College, Philadelphia New (Tenth) Edition Octavo of 1,404 pages, with 1,050 illustrations, some in colours Cloth, 45s net

McGuigan's Text-Book of Therapeutics

"Professor McGuigan has succeeded in producing a method quite different from the usual run of books on pharmacology and therapeutics suitable for undergraduates. One can unreservedly recommend the book to the attention of students of medicine in search of an accurate book of reference for their examinations."—SOUTH AFRICAN MEDICAL JOURNAL.

By HUGH ALISTER McGUIGAN Ph D M D, Professor of Pharmacology and Therapeutics University of Illinois College of Medicine Octavo of 600 pages, illustrated Cloth, 25s net

THE FOUR SYNOPSES (value 64s.) for 57s. 6d., postage 1s. 3d.; or separately as below.

5th Edition. Fully Revised and Enlarged. Crown 8vo. Over 1,000 pp. 21s. net. Postage 9d.

SYNOPSIS OF MEDICINE

By H. LETHEBY TIDY, M.A., M.D., B.Ch. (Oxon.), F.R.C.P. (Lond.), *Phys., St. Thomas's Hospital; Cons. Phys., Royal Northern Hospital.*

"Far ahead of any medical synopsis it has been our lot to encounter."—LANCET.

4th Edition. Fully Revised. Crown 8vo. 442 pp. With 171 Illustrations. 15s. net. Postage 6d.

SYNOPSIS OF MIDWIFERY & GYNAECOLOGY

By ALECK W. BOURNE, B.A., M.B., B.C. (Cantab.), F.R.C.S.(Eng.), *Sen. Obst. Surg., Queen Charlotte's Hosp.; Obst. Surg. Out-Patients, St. Mary's Hosp.*

"The book is to be recommended both to the student and to the general practitioner."—BRIT. MED. JOURN.

9th Edition. Fully Revised. With 163 Diagrams (some in colour). Crown 8vo. 684 pp. 17s 6d. net. Postage 9d.

SYNOPSIS OF SURGERY

By E. W. HEY GROVES, M.S., M.D., B.Sc. (Lond.), F.R.C.S. (Eng.), *Surgeon, Bristol General Hospital; Professor of Surgery, University of Bristol.*

"Deserves thoroughly all the success it has attained."—LANCET.

Crown 8vo. 262 pp. Illustrated. 10s. 6d. net. Postage 6d.

SYNOPSIS OF PHYSIOLOGY

By A. RENDLE SHORT, M.D., B.S., B.Sc. (Lond.), F.R.C.S. (Eng.), *Surgeon, Bristol Royal Infirmary*, and C. I. HAM, M.B., B.Ch., M.R.C.S., L.R.C.P., *late Demonstrator in Physiology, University of Bristol.*

"Provides in a compact, effectively arranged, lucidly expressed form an outline of physiology which will be helpful to all students."—MED. PRESS AND CIRC.

Third Edition. Fully Revised and Enlarged. Large 8vo. 500 pp. With 318 Illustrations, some in colour. 21s. net. Postage 9d.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.Eng., *Surgeon, Royal Northern Hospital, London.*

"An admirable book which we can recommend to all students."—BRIT. JOUR. SURG.
"We have nothing but praise for this book, which should be in the hands of every student."—EDIN. MED. JOUR.

Second Edition. Fully Revised. With 183 Illustrations. Demy 8vo. 350 pp. 15s. net. Postage 6d.

AN INTRODUCTION TO SURGERY

By RUTHERFORD MORISON,
M.A., D.C.L., LL.D., M.B., F.R.C.S.(Edin. and Eng.),
Consulting Surgeon, Royal Victoria Infirmary, Newcastle upon-Tyne; Emeritus Professor of Surgery, Durham University;

and CHARLES F. M. SAINT,
C.B.E., M.D., M.S.(Dunh.), F.R.C.S.(Eng.),
Professor of Surgery, University, Cape Town.

"No book could be read with more profit by the student new to clinical work."—LANCET.

Tenth Edition. Fully Revised. With 22 Plates and 345 Illustrations in the text, many of which have been redrawn for this Edition. 21s. net. Postage 9d.

PYE'S SURGICAL HANDICRAFT

A Manual of Surgical Manipulations, Minor Surgery, and other Matters connected with the work of House Surgeons and Surgical Dressers.

Edited by H. W. CARSON, F.R.C.S.(Eng.),
Late Senior Surgeon, Prince of Wales's General Hospital, Tottenham, and late Lecturer on Abdominal Surgery, North East London Post Graduate College

"Full of *information invaluable to the student*, the house surgeon, and the general practitioner. The book is exceedingly well got up, the illustrations are clear and helpful."—LANCET.

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd

LIPPINCOTT BOOKS

OPERATIVE SURGERY

General and Special Considerations

By Dr. MARTIN KIRSCHNER, Professor of Surgery and Director of the Surgical Clinic at the University of Tubingen, Germany.

Authorised translation by I. S. RAVDIN, B.S., M.D. With 746 Illustrations. Mostly Coloured. 50s.

The presentation of the first English edition of Kirschner's work is offered without apologies. A work so skilfully and beautifully illustrated fills a definite need in surgical literature. It is a book that will not only appeal to the surgeon, but also to the practitioner, who must do some of the minor surgery which is shown in this beautiful Colour Surgery.

Monographs on Surgical Pathology.

SURGICAL PATHOLOGY OF THE DISEASES OF BONES

By ARTHUR E. HERTZLER, M.D. 211 Illustrations. 21s.

There is no work which treats in a comprehensive manner with the pathology of the diseases of bones, and this book is the result of thirty years of medical teaching by the author.

SURGICAL PATHOLOGY OF THE SKIN, FASCIA, MUSCLES, TENDONS, BLOOD and LYMPH VESSELS

by ARTHUR E. HERTZLER, M.D. 260 Illustrations. Ready shortly. 21s.

Other volumes to follow.

CANCER

IN FOUR PARTS

Part I. CANCER IN ITS GENERAL RELATIONS.
Part II. CANCER RESEARCH.
Part III. REGIONAL CANCER.
Part IV. RADIUM AND RONTGEN RAY THERAPY.

International Contributions to the Study of Cancer. In Honour of JAMES EWING.

Edited by FRANK E. ADAIR, M.D., F.A.C.S. 163 Illustrations. 484 pages. Edition limited. 45s.

Fifty-four articles by world authorities on the subjects of Surgery, Radiology, Pathology, and Cancer Research.

EVERYDAY PRACTICE SERIES.

Ready shortly. Sold separately. 21s. per vol.
Edited by HARLOW BROOKS, M.D.

FUNCTIONAL DISORDERS OF THE GASTRO-INTESTINAL TRACT. By William Gerry Morgan, M.D., F.A.C.P. 32 Illustrations.

BACKACHE. By Lewellys F. Barker, M.D., LL.D., and John H. Trescher, M.D. 55 Illustrations.

POSTURE, Its Relation to Health. By Frank D. Dickson, M.D. 118 Illustrations.

HEADACHE. By William H. Robey, M.D.

Specially bound Reproduction from an old binding done in Cambridge in 1499. This series of Monographs is of personal application, and gives the actual results of the work of these great men.

Medical Catalogue sent post free on application.

E. & S. LIVINGSTONE, 16-17, Teviot Place, Edinburgh.

"THE CONJOINT FINALS." Being a Reproduction of all the Questions set in Medicine, Surgery, and Midwifery from 1911 to 1929 classified under the various systems and arranged in the date-order of their occurrence. By GERALD N. BEESTON, M.R.C.S.(Eng.), L.R.C.P. (Lond.). 6s. net; post free 6s. 6d.

"The book is intended to provide a sound scheme for general revision, and all students approaching that great crisis in their careers, the Finals, would do well to get hold of a copy."
—CHARING CROSS HOSPITAL GAZETTE.

A GRAPHIC GUIDE TO ELEMENTARY SURGERY.
By PROF. DR. TH. NAEGELI, Bonn. Translated by J. SNOWMAN, M.D., M.R.C.P. With Introduction by Dr. C. GARRE, Bonn. 322 Illustrations (mostly Coloured). 12s. 6d. net, post free 13s.

"In every single instance the picture shows what it is intended to represent, so much so that it would be quite possible for a student to go through the whole book and get a very fair idea of the elementary principles of surgery without ever reading a single word of the letterpress . . . We can most strongly recommend Professor Naegeli's *Guide*, both to the student and to his teacher. An excellent translation of the letterpress by Dr. Snowman furnishes explanatory comment wherever this is necessary."—BRITISH MEDICAL JOURNAL.

THE INTESTINAL PROTOZOA OF MAN. By CLIFFORD DOBELL, M.A., F.R.S., and F. W. O'CONNOR, M.R.C.S., L.R.C.P., D.T.M. & H. Published for the Medical Research Council. With 8 Plates (3 Coloured). 15s. net.; post free 15s 6d.

"The book should be read by every student of this highly specialized subject. It is the only up-to-date account of the human intestinal protozoa which exists.

MANUAL OF EMERGENCIES. Medical, Surgical, and Obstetric, Their Pathology, Diagnosis, and Treatment. By J. SNOWMAN, M.D., M.R.C.P. 10s net post free 10s. 6d. 2nd Ed.

"We are convinced that no general practitioner who has seen this work would willingly be without it."—POST-GRADUATE MED. JOURN.

ON WRITING THESES FOR M.B. & M.D. DEGREES.
By SIR HUMPHRY D. ROLLESTON, K.C.B., M.D. F.R.C.P. 1s. net; post free 1s 3d Second Revised Edition.

"One of the best of medico-literary first-aid manuals . . . should prove of great value to those who have to write theses, and we might add that many others would derive profit from reading it."—BRITISH MED. JOURN.

A SHORT HISTORY OF ANATOMY. By RICHARD H. HUNTER, Ph.D., M.D., M.Ch. 2nd enlarged edition 3s. 6d net, post free 3s 9d.

THE SEXUAL LIFE OF MAN. An Outline for Students, Doctors and Lawyers. By DR. PLACZEK, Neurologist in Berlin. Second edition, considerably changed and enlarged. Translated by Leslie Stuart Morgan, M.R.C.S., L.R.C.P. 12s 6d. net; post free, 13s.

"If the practitioner's library does not contain one of the older works on this subject, then we strongly advise him to accord a place to this very excellent translation."—JNL. OF CLINICAL RESEARCH.

ATLAS OF SYPHILIS. PROF. LEO V. ZUMBUSCH. With 63 Illustrations taken direct from nature by colour photography, and one single-colour illustration. 30s net, post free 31s. 6d.

CANCER AND RACE. A Study of the Incidence of Cancer among Jews, Conducted under the auspices of the Jewish Health Organization of Great Britain. By MAURICE SORSBY, M.D., F.R.C.S.E. With a Preface by Lieut.-Col. F. E. FREMANTLE, M.A., M.D., M.Ch., F.R.C.P., F.R.C.S., D.P.H., M.P. Demy 8vo. 7s 6d; post free 8s 3d.

"The work is a permanent contribution to the literature of cancer, and its statistical contents are likely to remain for many years the standard work on cancer among Jews."
—GENERAL PRACTICE AND FRANCO-BRITISH MEDICAL REVIEW.

OUTLINES OF SCIENTIFIC ANATOMY.
By DR. WILHELM LUBOSCH, Prof. of Anatomy in Würzburg. For Students of Biology and Medicine. Designed to supplement the usual Textbook Teaching. Translated by DR. H. H. WOOLLARD, M.D. 66 Illustrations. 21s. net; post free 21s. 6d.

"An excellent translation of an extremely valuable book, in which Professor Lubosch discusses, in a most illuminating manner, the broad lines of the science of anatomy."—EDINBURGH MEDICAL JOURNAL.

THE PRINCIPLES OF ANTE-NATAL AND POST-NATAL CHILD HYGIENE. By W. M. FELDMAN, M.D., B.S., M.R.C.P. Lond., F.R.S.Edin. With 161 Illustrations and 14 Plates, including over 100 Portraits. 25s. net post free 25s. 6d

"The author has attempted, and has succeeded in, the difficult task of producing a book which will interest alike laymen, physicians, lay workers at infant welfare centres, students of ante-natal care and welfare, and all concerned with the well-being of children."—BRITISH MEDICAL JOURNAL

THE IMMUNOLOGY OF PARASITIC INFECTIONS.
By WILLIAM H. TALIAFERRO, Ph.D., Professor of Parasitology, University of Chicago. Illustrated. 25s. net; post free inland 25s 9d. net; abroad 26s 6d.

"An important contribution to medical literature and one which should focus the attention of tropical workers in particular on the deficiencies and gaps in present knowledge of this important subject."—LANCET.

LABORATORY STUDIES IN TROPICAL MEDICINE.
By C. W. DANIELS, M.B.Cantab., F.R.C.P.Lond., and H. G. G. HENRY, C.M.G., M.D., M.R.C.P.Lond., D.P.H. 5th Ed. Thoroughly revised with many new and additional Illustrations. 25s. net; post free.

"A thoroughly practical guide to the student of tropical medicine, and is sure to maintain the popularity previous editions have enjoyed."—BRITISH MEDICAL JOURNAL.

The BEST INTRODUCTION to the HISTORY of MEDICINE.—Praised by all the Medical Press.

SIXTY CENTURIES OF HEALTH AND PHYSICK

Primitive Magic to Modern Medicine.

S. G. BLAXLAND STUBBS and E. W. BLIGH

with an introduction by SIR HUMPHRY ROLLESTON, Bt.

With 100 Illustrations. . . 15/- net.

"Certainly the most interesting narrative of its kind with which we are acquainted . . . . . We give this book more than average space in the belief that it is the best book of its kind for the student, lay, or medical."—*Medical Press and Circular.*

"To those who want an entertaining, reliable survey of medical history at an attractive price this book cannot be too highly recommended.—*American Journal of Medical Science.*

SAMPSON LOW

MEDICAL HYPNOSIS AND SUGGESTION

The following recent publications by EDWIN L. HOPEWELL-ASH, M.D., are now obtainable from BM/ELHA, London, W.C.1.

(1) THERAPY OF PERSONAL INFLUENCE: An ABC of Treatment of Personal Influence, Suggestion, Medical Hypnosis, and Psychomagnetic Methods. 2/9 post free. Includes notes of 114 successful cases.

(2) AN ABC OF MEDICAL HYPNOSIS. 1/1 post free. Outlines simple methods—essentially practical.

(3) PSYCHOMAGNETISM AND PERSONAL INFLUENCE IN TREATMENT. A B.M.A. address reprint; complimentary to medical practitioners

New and 19th Edition, thoroughly revised, of this Standard Work.

HANDBOOK OF PHYSIOLOGY

By the late **Prof. W. D. HALLIBURTON, M.D., LL.D., F.R.C.P., F.R.S.,** Emeritus Professor of Physiology, King's College, London, and

Prof. R. J. S. McDOWALL, M.B., D.Sc., F.R.C.P.(Edin.), Dean of the Faculty of Medicine and Professor of Physiology, King's College, London.

This classic work has been thoroughly revised, scarcely a page remaining unaltered, while the chapters have been re-arranged and a new index provided.

Physiological Abstracts.—"The book keeps up its reputation as a very readable and reliable exposition for students of physiology."

Science Progress.—"The outstanding features which characterise this textbook over and above its clear and complete exposition are balance and impartiality in the discussion of various explanations of physiological activities."

Nineteenth Edition, with 6 portraits, 4 coloured plates, and over 400 illustrations in the text. 18s. net.

JOHN MURRAY, ALBEMARLE STREET, LONDON, W.1

Third Edition

A TEXTBOOK OF

EXPERIMENTAL PSYCHOLOGY

By CHARLES S. MYERS, M.A., M.D., Sc.D., F.R.S., and F. C. BARTLETT, M.A

Demy 8vo. In 2 parts, complete. 16s net

The two parts are also sold separately Part I, Textbook, 10s. 6d. net; Part II, Laboratory Exercises, 7s. net.

"No worker in psychology can afford to dispense with this excellent textbook, while the physician opening it at random will find material to engross him on almost every page."—*Lancet*, on the Second Ed

CAMBRIDGE UNIVERSITY PRESS
Fetter Lane, London, E.C.4.

"Should be in the possession of every medical man."—*Glasgow Medical Journal.*

URINARY SURGERY

A HANDBOOK FOR THE GENERAL PRACTITIONER

By **W. K. IRWIN**, M.D., F.R.C.S.,

Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

¶ "Clearly written . . . furnishes the practitioner with information of great practical value in his everyday work."—*British Medical Journal.*

BOOKS FOR MEDICAL STUDENTS

NEW WORK. **READY SEPT. 17th.**

MODERN MEDICAL TREATMENT

By **E. BELLINGHAM-SMITH**, M.D., F.R.C.P.Lond., and **ANTHONY FEILING**, M.D.Cantab., F.R.C.P.Lond.

With an Introduction by **Sir HUMPHRY ROLLESTON**, Bart., G.C.V.O., K.C.B.

The subject of therapeutics is here presented from the aspect of the disease, and not from that of the remedies employed. In each instance a brief summary of etiology and symptoms precedes the details of treatment. While doing justice to the older methods the Authors have included all the recent advances in therapeutics which they have found serviceable. In his Introduction Sir Humphry Rolleston speaks of MODERN MEDICAL TREATMENT as an "attractive" work, "most conveniently planned for the reader's benefit."

Two Volumes, Demy 8vo. 1,432 pages. **30s.** net the set.

Radium Therapy: Principles and Practice.

By **G. E. BIRKETT**, M.C., B.A.Cantab., M.R.C.S.Eng. Illustrated. **17s. 6d.** net.

Safeguarding the Future

NOW, at the beginning of a medical career, is the time to consider what protection from everyday risks is necessary and the manner in which it shall be obtained.

Insurance, by means of first-rate policies, which can be arranged by the Medical Insurance Agency, provides a certain and inexpensive way of safeguarding against misfortunes of to-morrow.

The expense of a medical education is costly. A suitable Life or Endowment Policy will protect such cost if early death should occur.

Sickness and Accident Policies, to meet the case of entrants to the Profession, are recommended by the Agency, and full particulars will be sent on request.

Whatever your special needs, you are urged to communicate with the Agency which was founded in 1907 to assist members of the profession in all matters pertaining to Assurance and Insurance. Its advice is free and unbiassed.

What the Agency has done for the Profession.

SAVED by way of Rebates on Premiums over £45,000.

CONTRIBUTED to Medical Charities over £26,000.

THE MEDICAL INSURANCE AGENCY,

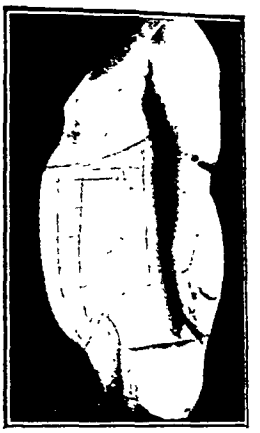
Non-Operable Hernia Can Be Controlled or Supported—Safely, Comfortably, Adequately.

The Spencer Supporting Corset and the Spencer Abdominal Belt for hernia embody all the features desirable and necessary in a garment to control or support inguinal, ventral, femoral, or umbilical hernia.

They fit perfectly; therefore they stay in position at all times, and give constant safety and comfort to the patient.



They are non-elastic; therefore they retain the hernia or prevent its protruding further.

They are strong; therefore they give great security.

They are washable; therefore they are sanitary.

They are durable; therefore they are economical.

They are designed for the individuals who are to wear them; therefore the physician can prescribe exactly what his patient needs.

Above is shown one type of Spencer Abdominal Belt, for the control of umbilical hernia.

The belt is made in two sections—a close fitting, long back, and a strong flexible front, attached to the back by a set of straps and buckles which also give adjustment.

Our medical department will supply booklets on the use of Spencer Supports for the relief of movable kidney, enteroptosis, hernia, chronic intestinal stasis, sacro-iliac strain and for maternity wear. *Use the coupon below. We shall be glad to send you any or all of these booklets.*

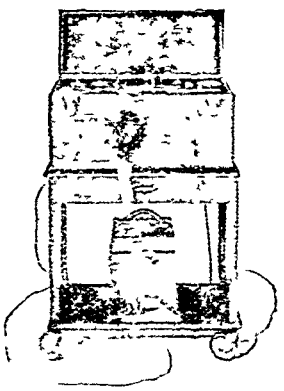
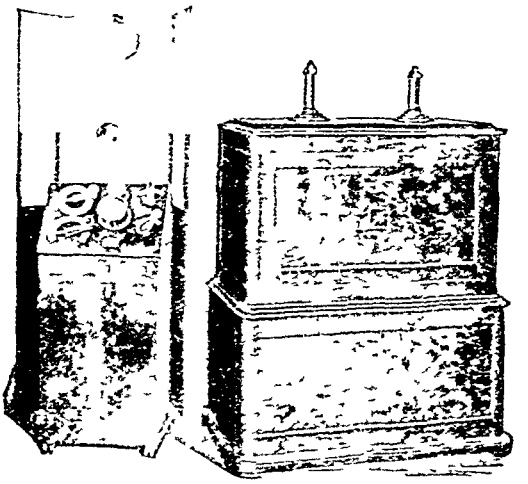
IMPORTANT ANNOUNCEMENT



A new range of Hanovia Actinotherapy Apparatus fully adapted to meet every modern need is now offered for your service



These new models incorporate some very important changes. They set a new standard of value in the field of actinotherapy equipment, being easier to operate, better finished and of higher efficiency—thus achieving better therapeutic results.

The two new booklets, "What is Modern Actinotherapy?" and "New Models of Hanovia Lamps," fully describing the subject and the lamps themselves, should be in the hands of every Medical Practitioner. They are free to all professional enquirers. Send for them to-day, marking your enquiry Dept. 9.

Equipment and service also through all electro-medical dealers.

The Victor Electrocardiograph—sensitive—accurate—fool proof

The Victor Snook—the X-ray by which all others are judged

The Vario frequency—one of three Victor diathermy machines

For Optimum Results—Own Victor

IF there is anything that leads to better results in the practice of physical medicine than owning one piece of Victor apparatus—it is to be completely Victor equipped—one piece of Victor equipment more often than not leads to a complete laboratory.

It is because all Victor-made apparatus, whether for X-ray, physical therapy, or cardiography, is so essentially better and of higher quality than any other.

It has superior design, gives better results, and is accompanied by better service.

To-day there is a Victor machine for every important field in which electricity is of aid to the medical profession.

In physical therapy, electrocardiography, and X-ray the name Victor stands for optimum results. The initial cost in some cases may be a trifle greater, but it is more than repaid in longer service and better results.

We welcome your enquiry on any electro-medical problem.

VICTOR X-RAY CORPORATION, Ltd.

15-19, Cavendish Place (Cavendish Square), London, W.1

GLASGOW MANCHESTER BRISTOL

X-RAY YOUR PATIENTS

wherever they are at surprisingly low cost—

Negatives developed within 10 minutes—perfect results assured

X-ray examinations can now be made at the patient's bedside—anywhere—at any time. Powerful portable apparatus is available day and night for service—under the control of expert radiographers—and within forty minutes of the arrival of the Service Car at the door of your patient's house, negatives are ready for inspection. The films are developed on the car, which is fitted up as a dark room—and the taking of the radiographs can be conducted throughout under the supervision of the medical practitioner concerned. Great penetration of any part of the body is ensured, and the definition of the negative is rendered equal to that of any permanently installed apparatus.

During the last seven years over 1,000 doctors have availed themselves of X-RAY CAR SERVICE.

Full details in the form of an interesting descriptive booklet, will gladly be sent on request.

Write, wire, or telephone to-day

The charges are graded according to the distance travelled from London—the basic charge within a 10 miles radius being only four guineas, and one guinea for each subsequent radiograph at the same visit. Special terms for hospitals.

SALTAIR SURGICAL SERVICE

THE SALT TRADITION

ONE hundred and thirty-eight years of close co-operation with the Medical Profession, and an ever-active interest in the progress of Modern Surgery, has established for the House of Salt a reputation for supplying every type of Surgical Appliance—specially made for each individual case and with the greatest accuracy of detail to the attendant Practitioner's prescription.

Such a Tradition has been achieved by the accumulation of knowledge of five generations of the House of Salt, who, in their co-operation with the Medical Profession, have offered in the past, and still offer, their services in the making of experimental appliances at their own expense.

The fact that our unique Guarantee is rarely taken advantage of is proof positive of our ability correctly to interpret medical requirements.

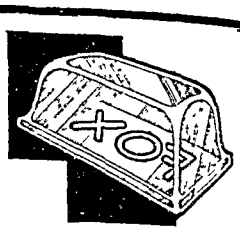
COMBATS RHEUMATISM BY BANISHING AUTO-INTOXICATION

The prevalence of such maladies as rheumatism, lumbago and neuritis is now generally recognised as being, in many cases, directly attributable to auto-intoxication arising from constipation. Sal Hepatica is a proved, medicinal, effervescent saline which stimulates the bowels to peristaltic action ensuring the elimination of all toxic waste products. Its sodium phosphate content increases the secretion of bile, thus restoring the daily habit of defecation by natural means. Unlike many other laxatives therefore increasing dosage is unnecessary. Sal Hepatica does not cause depression, griping or weakness.



Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Company.

ENGINEERING PROBLEMS IN ABDOMINAL DISPLACEMENTS SOLVED BY SURGICAL BELTS

The medical profession is beginning to realise that when it is a matter of internal displacement, abdominal disorders will not yield to stimulation or lubrication from within. These methods ignore the mechanical problems which would be the first consideration of an engineer called upon to conserve the function and structure of a coiled, mobile and valved tubing such as the alimentary system. The solving of these problems is the first consideration in the construction of Domen Surgical Belts.

These Belts correct and prevent mechanical faults in the engineering system of the abdomen by counteracting with upward support the downward pull of gravitation. And to do this Domen Belts rest upon the only anatomically legitimate foundation—the bony pelvis. *Domen Belts are designed for specific complaints. They fit well* and comfortably. They leave the patient free and unembarrassed. Your card or a telephoned request will bring you full particulars.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

SUPPLIED in WIDTHS

THE DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

AN INTERESTING COMPARISON

SOYOLK

FOR BUILDING

BONE — MUSCLE — NERVE

Soyolk is a highly digestible and pleasantly flavoured flour prepared from the Soya Bean, and is used largely in some of the leading hospitals and sanatoria. The nutritive value of this STARCH-FREE product is shown in the following comparative analysis.

	WATER	PROTEIN	FAT	CARBOHYDRATES	ASH	CALORIES
	%	%	%	%	%	per lb.
SOYOLK	9	42	20	25 (No Starch)	4	2165
FINEST WHEATEN FLOUR	13	12	1½	73 (70% Starch)	½	1750

SOYOLK FINEST WHEATEN FLOUR

The inclusion of Soyolk in some of the common farinaceous foods such as bread, confectionery, puddings, porridge, etc., adds substantially to their nutritional value and converts a merely carbohydrated food into a perfectly balanced article of diet.

Apply for free sample and literature to:

THE SOYA FLOUR MANUFACTURING CO., 7, MINCING LANE, E.C.3.

'PANOPEPTON'

WHAT IT CONTAINS.

Contains in solution, in an agreeable form, the entire nutritive constituents of beef and wheat.

Contains all that is digestible in beef—in its juice and in its muscle tissues.

Contains all that is digestible in wheat—its gluten, its carbohydrates.

Contains all the savory and stimulating elements, the extractives, the mineral constituents of beef and wheat.

Contains these constituents in the soluble, perfectly diffusible form into which they are converted in the process of normal digestion.

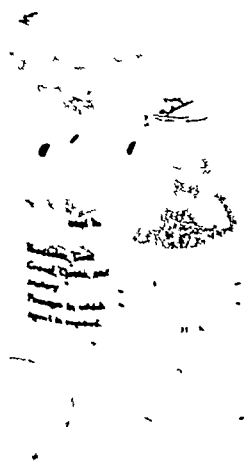
USES OF 'PANOPEPTON.'

Can be relied upon in cases where the nutrition of the patient is of prime importance.

Has saved the patient in desperate straits due to intolerance of food.

Has nourished and restored in many cases where the patient has steadily lost strength on other foods.

Possesses remarkably restorative and stimulating properties.



Is the most nutritious, the most agreeable and reliable—the BEST of all foods for the sick.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime. SUPPLIED IN 12-oz. BOTTLES.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassium et Sodii Citro Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism
The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal

WHEN THE PATIENT'S RECOVERY IS HAMPERED BY ANOREXIA . . .

these essences supply stimulus and energy without strain to the digestive system . . .

BECAUSE they are suave and non-irritant in action; because recent scientific tests have shown that they can be assimilated by the digestive organs forty minutes quicker than ordinary foods and without the formation of any residue, Brand's Essences of Beef or Chicken have come to be a preferred invalid food.

99 out of every 100 doctors recently interviewed recommend them in cases of intestinal disturbances, in states of exhaustion, in specific fevers, in all disorders associated with pyrexia, and before and after operations.

To-day doctors everywhere are finding these Essences indispensable in the post-influenzal state because they supply energy quickly and prepare the system to accept a more solid diet.

Brand's Essences of Beef or Chicken are prepared by an exclusive process from the finest freshly killed English meats without the addition of colouring matter or preservatives. Patients welcome them because they are delicious to taste and easy to swallow.

Samples will be gladly sent on receipt of a professional card. Brand & Co., Ltd., Dept. F37, Mayfair Works, South Lambeth Road, London, S.W.8.

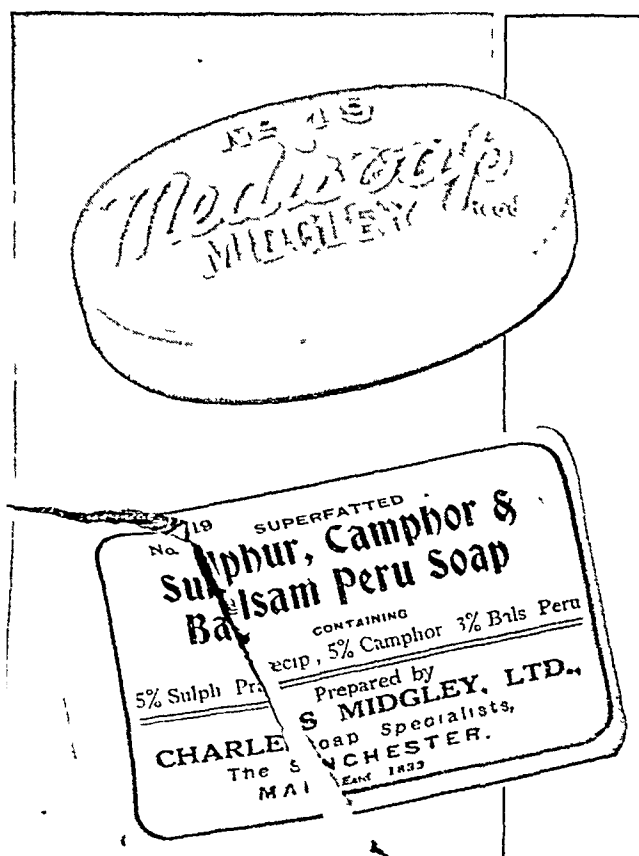
ACCEPTED AMERICAN MEDICAL ASSN Council on Pharmacy and Chemistry

IN URINARY INFECTIONS

Pyridium has all the qualifications of an ideal urinary antiseptic—it is chemically stable; it is non-toxic and non-irritating; it exerts an antiseptic action in high dilution in either acid or alkaline urine; it is early and gradually eliminated in the urine in sufficient concentration to exert a continuous local antiseptic action; it is administerable by mouth.

Pyridium exerts more than a local effect—it penetrates the tissues and reaches the submucous areas not ordinarily accessible to therapeutic agents.



TRADE **PYRIDIUM** MARK

Effective in coccal, B. Coli and mixed infections, Pyridium is indicated in cystitis, pyelitis, urethritis, prostatitis, epididymitis, vaginitis, cervicitis, salpingitis and gonorrhoea.

Pyridium is the registered trade mark of the Pyridium Corporation of New York, to designate its preparation of phenyl-azo-alpha-alpha-diamino pyridine hydrochloride.

Literature and REDUCED prices of Pyridium products on request.

MENLEY & JAMES, LTD., 64, HATTON GARDEN, LONDON.

Medisoaps

MIDGLEY'S MEDICATED SOAPS

SKIN medication by means of "Medisoaps" is free from the discomforts of ointments, a fact which is of marked importance in skin and scalp diseases for which Medisoaps are ideal. Whilst No. 19 Medisoap, as illustrated, is very popular, the full list of Medisoaps affords a wide choice of formulæ.

A Prescriber's Index, relative to the comprehensive range of Medisoaps will be forwarded on application to.—

EVANS SONS LESCHER & WEBB LTD.

Regesan

CREAM of MAGNESIA with LIQUID PARAFFIN

(CONTAINS 30% LIQUID PARAFFIN)

A STABLE well-balanced combination containing 30% Liquid Paraffin held in suspension in a finely divided state. Its consistency is such that the tendency to leak exhibited by Liquid Paraffin is eliminated. Regesan Cream of Magnesia with Liquid Paraffin provides suitable treatment for all digestive troubles with which constipation and hæmorrhoids are associated. It is certainly the ideal laxative during pregnancy and lactation, and is suitable for infants and children.

Doctors, Nurses and Hospitals all over the world put their faith in MARSHALL'S—a faith that has been justified by 40 years of unfailing efficiency and uniformity.

Sample free on request to members of the medical and nursing professions.

LYSOL LTD., Dept. K18b, RAYNES PARK, S.W.20.

Lysol

THIS NAME— GUARANTEES SAFETY

The name MARSHALL'S guarantees purity, efficiency, uniformity in every bottle of Lysol you purchase. There are other Lysols to be had, but MARSHALL'S is the only Lysol made to the original formula.

MARSHALL'S is better because it allows a greater margin of safety. In the correct dilution its bactericidal power is certain, yet it is harmless to the most delicate tissue. MARSHALL'S Lysol is the most widely used antiseptic for Obstetrics, Gynaecology, etc., because it is ideal for these purposes.

ONLY THE PUREST INGREDIENTS

All the ingredients of MARSHALL'S Lysol have to conform to the most rigid specification. Every stage of manufacture is subject to strict and constant supervision and analysis to ensure a product worthy of your recommendation.

MARSHALL'S Lysol

The French Natural Mineral Water.

VICHY-CÉLESTINS

And the other State Springs of Vichy.

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

OVALTINE

FOR THE GROWING CHILD

"Ovaltine" is indicated as a means of promoting normal growth and development when the weight of the child under observation is less than that which statistics show a child of the same height should weigh.

The physician has only to consider the composition and properties of the product to recognize how suitable it is as a building and reconstructive nutrient.

"Ovaltine" is a concentrated extraction of malt, milk, and eggs in the form of golden brown granules. For tissue growth or repair it provides proteins, mineral constituents, adequate energy value, and the Accessory Growth Factors or Vitamins in correct nutritive ratio

Children love the deliciousness of "Ovaltine" and thrive remarkably well upon this complete food. It is of unsurpassable value as a meal-time beverage in place of tea, coffee, cocoa, or other beverages.

English Trade Mark No. 276477 (1905)

Local Anaesthesia in Surgical Practice

SEPTIC ARTHRITIS.

Typical Case.

Mrs. E. C. H., aged 45 years.

Diagnosis: Septic Arthritis of left hip.

Operation: Arthrotomy and drainage.

Anaesthesia: Local infiltration, 180 c.c. of 0.5 per cent. Novocain-adrenaline solution.

Operation: Patient was given an injection of scopolamin 1/200 gr. and pantapon 1/3 gr. two hours before the operation and one hour before. Infiltration was made along the lateral aspect of the thigh and a longitudinal incision was made down to the abscess cavity. 500 c.c. of creamy pus escaped—the finger was introduced and the hip-joint was explored. A long curved forceps was introduced, and after infiltrating the fluteal region an incision was made down to the forceps. Dakin's tubes were introduced through the counter opening and passive motion was carried out daily. The patient was discharged with a movable hip.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

Nutriment in an appetising form

SO many items a doctor would like to include in the sickroom diet fail to appeal to the difficult appetite, that the dietary often represents one of the greatest problems.

That problem does not exist with Ryvita Crispbread. In it you have an article, the crisp scrunchiness of which has an irresistible appeal even to those whose appetite is flagging, an article moreover which both from its chemical nature and its physical form promotes great ease of digestion. Its crisp form compels thorough mastication, while the fact that it contains the natural "roughage" of the grain is of great assistance in preventing constipation.

As to its food value, it need only be said that it consists entirely of pure whole-grain rye, rich, as is well known, in the salts of iron, phosphorus, and calcium, and marked by a very high vitamin B content.

We shall gladly send a free carton, full analysis and other particulars, to any interested Member of the Profession.

Ref. AS/DM

July, 1931.

To Members of
The British Medical Association.

Dear Sirs,

A new protection for the public has been devised by the American Medical Association under governing rules for the approval and acceptance of Food Products.

We feel sure you will be interested to learn that Libby's Evaporated Milk has been submitted to the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association, and we are proud to say, has passed the test successfully, so that we feel more confident than ever in offering it as the best foundation for Infant Feeding.

On the accompanying sheet you will find the report of the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association.

Clinical data will be gladly supplied on request,

Yours truly,
Libby, McNeill & Libby, Ltd.

Libby's Evaporated Milk conforms to the English Standard which requires no less than 9% of butter fat and 31% total milk solids. See opposite page for analysis.

REPRINTED FROM THE JOURNAL

COMMITTEE ON FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COMMITTEE ON FOODS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, *Secretary*.

LIBBY'S STERILIZED UNSWEETENED EVAPORATED MILK

Manufacturer.—Libby, McNeill and Libby, Chicago.

Description.—An unsweetened evaporated milk.

Manufacture.—The milk is collected under prescribed conditions of sanitation, strained, cooled to 60° F. or under and delivered to the condensary each day. The delivered milk is tested for odor and acidity, a 'reductase test' with methylene blue is applied. Speed of destruction of the color is indicative of cleanliness and the previous treatment. Unsatisfactory milk is rejected. A bacterial count is made each week of a composite of samples of all deliveries.

The accepted milk is passed through steam heated coils into stainless steel or glass-lined tanks. The heated milk is concentrated in vacuum pans at a temperature of from 130° to 135° F. The low temperature and absence of air has little destructive action on vitamins A and B (complex). The concentrated milk is homogenized by forcing under high pressure through small apertures, which disperses the fat in fine globules and prevents separation during storage.

The homogenized milk is cooled to 40–45° F. and standardized to comply with U. S. Department of Agriculture standard for evaporated milk. The standardized milk is fed through pin-hole openings into the cans which are automatically soldered.

The sealed cans are processed under steam pressure at 240–242° F. for not less than fifteen minutes with a twenty minutes' "bringing-up time," immediately after which they are cooled to room temperature. After a short storage time the cans are inspected and labelled.

All the equipment and the entire plant are kept under strict sanitary conditions.

Chemical Composition.—

	(*proximate analysis*)	*per cent.*
Total solids	.. ..	26·1
Ash	.. ..	1·54
Protein (N 6·38	.. ..	7·2
Fat (ether extract)	.. ..	7·9
Lactose	.. ..	9·5

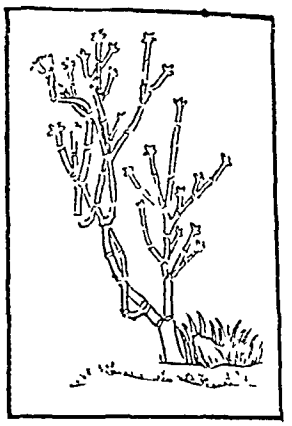
Calories.—

1·38 per gram
39·2 per ounce

Vitamins.—Diluted with an equal volume of water the vitamin A and B (complex) potency approximates that of usual milk.

Micro Organisms.—The product is sterile.

Claims of Manufacturer.—Libby's Evaporated Milk is clean, easily digestible and contains practically all the nutritive values of ordinary milk, which it approximates when diluted with an equal volume of water. It is recommended in infant feeding. The curds formed in the stomach are smaller, softer and more easily digestible than those from raw or pasteurized milk. It may be used in cooking and baking as is ordinary milk.



CHEMICAL COMPOSITION OF LIBBY'S MILK UNDER ENGLISH STANDARD

Total Solids	31%
Butter Fat	9–9·4%
Milk Sugar (Lactose)	11·2–11·7%
Protein	9·2–10%
Ash	1·6–1·8%

To attain the English Standard 65% of the natural water content is removed.

Ephedrine in Asthma and Hay Fever

At this season Ephedrine becomes of particular interest for the treatment of hay fever. Whilst 'Tabloid' Ephedrine Hydrochloride, taken orally, is specially indicated, other products are provided for injection and local application

"AT TWO MONTHS HE WEIGHED ONLY 2½ lbs"

COW & GATE AGAIN PERFORMS A MIRACLE!

Devon Cottage, Upper Dicker,
To — Hellingly, SUSSEX.
COW & GATE LTD., 19th January, 1931

Dear Sirs,

I feel I must write and tell you what Cow & Gate has done for my baby boy.

He was prematurely born (7 months) and weighed 4½ lbs. He developed jaundice from over-long exposure and gradually lost weight, till at 2 months he weighed only 2¼ lbs. For ten weeks he was in a Nursing Home where they tried various foods with no success, he would vomit every feed.

I had him home in a dying condition, nothing but a little frame of bones, no flesh whatever, and no warmth in his body at all. I had to keep him between hot water bottles always. For weeks I tried different feeds, and one day I was recommended to try Cow & Gate and from the first feed he began to thrive, his bowels worked naturally for the first time and he ceased to vomit, so that I knew at last that he could digest his food and he gradually put on weight (average 1 lb. per month) and now at eleven months he is quite a nice little baby with two teeth.

I cannot express my gratitude sufficiently to Cow & Gate, but everyone around here can testify to what it has done for him. I feel it saved his little life.

Yours faithfully,
(Mrs.) Gertrude Peckham.

Cow & Gate Milk Food

has, it is said, saved more baby lives than any other preparation in the world

THE PRELIMINARY SCIENCES IN MEDICINE

A PLEA FOR A NEW OUTLOOK

BY

R. J. S. McDOWALL, D.Sc., M.B., F.R.C.P.Ed.

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF LONDON; KING'S COLLEGE; EXAMINER IN PHYSIOLOGY FOR THE UNIVERSITY OF LONDON, THE ROYAL COLLEGE OF PHYSICIANS, AND THE ROYAL COLLEGE OF SURGEONS

hundred and fifty years ago there were many more stitutions teaching medicine than at present, they were r the most part places where instruction was given in natomy and materia medica, but only these survived hich had the foresight to become associated with schools science that provided the necessary instruction in emistry, physics, zoology, and botany. During the last entury there have been more and more additions to the me honoured teaching of Sydenham, which depended olely on clinical observation, until so great a part do ne sciences play in modern medical education that the edical student spends almost half his time in studying iem.

MEDICINE THE MAKER OF SCIENCES

The preliminary sciences themselves have greatly ultiplied. From anatomy, or the study of bodily tructure, has developed physiology, the study of func ion, and, from the latter, biochemistry, the chemistry f living processes, and pharmacology, the nature of the ction of drugs. We may recall that in the last three undred years medicine has taken a large part in the evelopment of chemistry and biology. All these subjects ave now become completely independent sciences pur uing knowledge for its own sake irrespective of the needs f medicine. Nor has medicine come to the end of making ew sciences. In the near future we may expect to see he subject of symptomatology, for example, receive more nd more attention. At the present time there is an normous hiatus not only between the sciences and clinical ork, but between medicine and surgery, and much would e gained if a systematic effort was made to take advantage f the opportunities of surgery and to bring the facts thus ollected into medicine. For example, some physicians alk a great deal about toxæmia and auto-intoxication ut how many have investigated the effects of a severe urn or simple septic condition upon the general health? ow seldom, indeed, is a blood pressure apparatus avail ble in a surgical ward, although surgery presents almost nrivalled facilities for the study of blood pressure. The ajority of surgeons have not the time, the training, or he incentive for such research, and much valuable in formation is lost. They are too busy—making a living! I prefer to call this new subject a science, for it is evident that a large amount of information would be obtained which would not necessarily be of immediate practical value. So far the subject has been studied by individual workers for their own interest, some clinical and some not.

GROWING INDEPENDENCE OF SCIENCES

As the early medical sciences gradually developed along their own lines the physician and surgeon lost touch with their work. If we can judge by the writings of thirty years ago, it would almost appear that a certain amount of resentment grew up on the part of the clinicians who saw their children develop into somewhat obstreperous adolescence and full of determination to make their subjects often at the cost of considerable material loss. At a complimentary dinner given to one of our most distinguished physiologists he recalled the difficulties of the relatively recent makers of physiology. Often the pay ment of the laboratory boy was the carcass of the rabbit used in the experiments. Medicine has good reason to admire and be grateful to those pioneers of medical science.

Twenty-five years ago it was fashionable for clinicians to scoff at the early scientific teaching to students. I have beside me an address by a distinguished physician who gives four examples of the futility of physiological teaching. Succeeding years have already shown how limited was his vision, for each of his 'futilities' has borne rich fruit in medicine. One was the then physiological curiosity—the current of action produced when a muscle contracts. Little did he realize that this curiosity would soon become the basis of electrocardiography. Again, a great surgeon once told the members of his class that now they had come to the wards they must put their science behind them. He was reproached by the local professor of physiology, but with characteristic wit and skill he escaped by replying 'Ah, my dear professor, I meant that they were to put it behind them as a *tu a tergo*.' It is pleasing to record that he has since indicated that he does believe in physiological science as a real force even in surgery.

In this connexion it is interesting to recall that some of the great advances in the sciences have not been followed immediately by their obvious application clinically. For example, surgeons continued to remove the whole thyroid for twenty years after Schiff had shown in dogs

that its removal resulted in myxoedema, while we read that Harvey's discovery of the circulation of the blood had no effect on current medical teaching, including that of the great Sydenham, whom, with Boerhaave in Leyden, we look upon as the parents of post-Renaissance clinical medicine. Fortunately such days are now remote.

SCIENCES NOT VOCATIONAL

At the same time we must not imagine that the preliminary sciences are entirely free from the indictment made against them that they do not serve medicine so well as they might, but let it be said at once the fault is as much that of medicine. All the preliminary sciences have grown enormously since they were introduced into the medical curriculum. The medical student receives a course similar to, but less concentrated than, that of the student preparing for a degree in science, and he has to make the best of it; the state of affairs obtaining in many universities bears very little relation to the vocational needs of medical students. It is generally agreed that this arrangement is in some respects ideal, or was so thirty years ago; but, as will be discussed below, how far this non-vocational outlook should be carried is now a very debatable problem, for the sciences are inclined to be taught at the expense of the vocational needs of medicine. This is particularly true of botany, zoology, chemistry, and physics, and is only to be expected when we remember that these departments have to consider many students who will pass on to fields other than medicine, and that the students who are going to continue these subjects in later life are regarded as having first claim.

It is only with the greatest difficulty that the material suitable for science students can be selected, and many strange anomalies exist. For example, the term chemistry in the intermediate examination in science of the University of London does not include organic chemistry, although this examination is the sole intermediate examination in chemistry for a student passing on to honours in physiology, and exempts from the whole chemistry examination for many degrees and diplomas. If those responsible for the science curricula find it difficult, how much more difficult it must be when non-medicals attempt to devise a course for a profession of which they know very little.

BOTANY A RELIC

Botany is an anachronism in the medical curriculum and a relic of the days when the doctor prepared his own drugs from plants, but its retention is insisted upon by those who, knowing little of the composition of a present botany course, feel that somehow it may have some cultural value. They do not realize that one of the chief considerations of botany teachers is to prepare students whose prospect is for the most part the teaching of botany in girls' schools, botany being one of the more polite subjects. In zoology the keynote is still the Huxley types, which are laboriously memorized, and from which the student rarely comes away with much idea of why Huxley emphasized these types or of the great principles of biology.

It cannot be denied that some of the details taught in botany and zoology have a relation to medical work, but in many instances they have little relation to biological principles and are merely crammed for examination purposes and should not be taught. For example, the details of flat and round worms could with advantage be deferred, since they are of greater interest in parasitology. In botany the details of moulds and bacteria could just as well be postponed until the student takes bacteriology. Teachers of these subjects are sufficiently astute to include such matters in the examination for obvious reasons, but they are quite oblivious of the psychological (really biological) consideration that isolated and unrelated facts are extremely difficult to retain except by those of Eastern descent with prodigious memories.

UNDUE DETAIL HARMFUL IN EARLY YEARS

It can indeed be claimed that not only is the requirement of such detail at this stage useless, but it is actually harmful, as it gives the student the idea that he must memorize rather than understand. Those of us who meet students later know that their outstanding characteristic is that they have committed to memory more than they really understand, and as a result their knowledge is in compartments. If they are asked a question in the way they have crammed it they answer volubly, but if the same question is turned the other way round they are strangely silent. This criticism is true, unfortunately, of much so-called education other than medical. It is probable that the old-fashioned natural history was much more valuable as a preliminary to medical education than what is taught at present, as it gave students a real interest in biological problems.

The physiologist, coming into contact with the students in their second year, is in the unfortunate position of seeing how completely inadequate is the first-year teaching. The student comes to him possibly with an excellent idea of the blood vessels of the frog or the bird, but with quite an insufficient knowledge of the mammal. There is a good deal to be said for the study of human anatomy before comparative anatomy. What a great advantage it would be if the mammal was more fully studied, especially with regard to relation of organs and the possible effects of erect posture. The gross errors committed in chemical physiology make it evident that if more attention was paid in the first year of chemistry to technique in weighing, measuring, and handling materials, instead of collecting scattered facts, an enormous advantage would accrue which would be of value throughout the rest of the student's life.

ANATOMY AND PHYSIOLOGY

Nor are anatomy and physiology free from similar defects. Some years ago it was my fortune to take part in clinical teaching, and it will be generally agreed that the student passes on to the wards insufficiently prepared. Under the present system it is practically impossible to avoid this. It would be almost possible to divide the facts of physiology into two categories: those which are essential to medicine and those which are not so essential—for example, the heart sounds and the measurement of the hydrogen-ion concentration of the blood. Suppose questions on these two subjects appear in an examination paper and the pass mark is the usual 50 per cent. It is quite common for students to know much about the latter question and nothing about the former, and, according to custom, to pass; yet it will be agreed that a student who does not know anything about the heart sounds ought not to be allowed to pass to clinical work, but in the science of physiology hydrogen-ion concentration is more important than the heart sounds. It is common for a man to fail in a final examination because he does not know an elementary fact, but this does not occur in the preliminary sciences, nor is it possible, because what is a necessary fact for the science of physiology is not essential to medicine, and vice versa. The student himself cannot be expected to differentiate.

This example brings home to us the difficulty of the present system of teaching the sciences in medicine. The relative importance of the same facts may appear quite different to the science concerned and to medicine; to look from the point of view of the science may be the better culturally but detrimental vocationally. That, at first sight, may not appear serious until it is realized that

student badly educated vocationally in the rudiments undamentally unsound throughout the rest of his course l wastes the time of his teachers and of himself. nicians who have to inculcate elementary anatomy and ysiology upon students in the wards appreciate this as ich as the chemical physiologist or pathologist who has teach students how to weigh and measure.

Having criticized my own subject, I feel that anatomy nnot escape censure. May one ask—Would even the erage surgeon be any the worse if he only knew half e anatomy required for the Second M.B.? Need he ow the relations of even such a large structure as the ominate artery, which he is never likely to have much terest in again except in the post-mortem room, not to eak of many details about bones? Many students who ve not a good visual memory have the greatest difficulty amassing the vast amount of detail required; moreover, is promptly forgotten. We have only to ask ourselves w much we remember of the anatomy we knew to alize the truth of this statement. Surely it would be great advantage if more time was spent on the study movement. The average doctor might then be at least little more capable of treating a multitude of football juries which at present find their way too often into te hands of bone-setters and osteopaths. I know that am raising my voice against a time-honoured tradition, nd we all must honour the tradition which has brought s successfully, thanks to Vesalius and his successors, ut of the Dark Ages when anatomy was at a very low bb. In preserving the Vesalian tradition in teaching o-day, however, we must be careful that we do not lace ourselves somewhat in the position of those who urned Servetus at the stake because by discovering the ulmonary circulation he struck a vital blow at the great nd honoured tradition of Galen which had stood unallenged for actually a thousand years.

Why not let us have a 75 per cent. pass mark on a aller field of knowledge and a 40 per cent. pass mark matters less essential vocationally? This would unoubtedly lead to a generally increased proficiency, hough it might make it more difficult for examiners to fferentiate between the best candidates. The present stem by which an enormous amount of information may required leads to a vast amount of gambling which has ade it necessary for certain questions to be compulsory en in the London M.B. Students, for example, in ysiology often find it more profitable to omit reading e nervous system altogether, especially where there is me choice of questions. In this connexion we should member that a course in Medicine is different from a urse in Arts, or even Science, as it is for many students eir sole preparation for the task of treating patients, nd it is of national importance that there should be a inimum all-round efficiency, and that the time of train-g should be used to the best possible advantage.

It is easy to criticize, but in doing so we must not be nfair to those who have gone before us, and we must member that the general lay-out of the medical rriculum was made when many of its subjects were ry much smaller than they are now. All was then ne for the best. It may be said that it is educaonally good for the student to learn a great deal of hat is really unnecessary, but are we entitled to teach uch that is unnecessary while the curriculum is so overowded that he has scarcely time to think and while we ve to omit a great deal of what would be really useful general practitioners of medicine? Even if we may ach him some facts that are not essential, is it not best teach those things which are in most immediate relationnp to his later work? If he must learn about iron, is it t better for him to learn about the function of iron as emoglobin in the body than to learn how the mineral is obtained from natural ores and converted into steel, however interesting it may be? We cannot make the medical course longer, for it would be an uneconomical proposition not only financially, as it would reduce numbers entering, but because there is a limitation to mental capacity; the evidence is very complete, and indeed it is our common experience that we reach a stage when we can only accumulate new information at the expense of some which we already have.

There is very little doubt that the existing methods of teaching the preliminary sciences merely give the student a loathing for them which may never be dispelled, instead giving him an absorbing interest in the wonderful processes of nature on which his future knowledge will be based. The preliminary sciences have many fascinating problems in common with medicine which are of the greatest possible educational value, but if they are taught at all they form a very minor part of the teaching. In biology there is the problem of heredity, the relation of structure to function and adaptation to environment. In chemistry there are the great problems concerning the passage of substances through membranes; their study would afford excellent training and would also be useful, but they are almost omitted from the usual chemistry course. Such examples could be multiplied indefinitely, but those given serve to indicate that the preliminary sciences might serve medicine more adequately without losing their own dignity.

PURE SCIENCE NECESSARY IN MEDICINE

During this discussion we must be clear that we do not confuse research in the medical sciences with teaching, for there is much evidence in medicine that purely scientific research has proved extremely useful. When von Mehring and Minkowsky removed the pancreas *to see what would happen* they did not suspect that their findings would lead to a treatment of diabetes, nor did Halliburton and Rosenheim, when they studied the chemistry of nervous tissues, imagine that the facts which they collected would lead to a cure for rickets. We may recall Sprat's *History of the Royal Society*, in which he says:

> "If they will persist in contemning all experiments except those which bring them immediate gain and a present harvest, they may as well cavil at the providence of God, that He has not made all the seasons of the year to be times of mowing, reaping, and vintage."

The sciences must be taught to the medical student, because the methods of science are the methods of medical research, and they teach him to think clearly and logically. But they must not and need not be taught *at the expense of his vocation*, and in most instances the principles of a science can be taught, using examples which are of the greatest medical interest and importance. It is not enough to give a medical student a smattering of a science and to cram him with details for this or that examination. That is not education, although it is what commonly goes by that name. The student must be taught primarily to think and to weigh evidence. It would be well if every ten years the syllabus was reviewed to ensure that this principle was being maintained, for there are constant changes in the possibilities of correlation between the preliminary sciences and medicine. It is doubtful if the teachers of these sciences are always capable of judging what should be taught, as they are often not medically qualified; frequently they are juniors in scientific departments waiting for posts in pure science who may have little real interest in medical requirements. There is an increasing need for good chemists, physicists, and biologists who will devote their full energy to the needs of medical teaching and research rather than to pure science. In Scotland some of the universities are already provided with senior posts for this purpose.

As the years go on more and more competent teachers will be required in the preliminary sciences, for these sciences are gradually extending into the clinical years. The establishment of full-time chairs of medicine and surgery is an indication of the requirements of the sciences in more intimate association with the study of disease. For example, our greatest need to-day in the investigation of cancer is a more comprehensive knowledge of the fundamentals of normal growth and repair; and thousands of persons die annually from surgical shock because of our ignorance of the control of the circulation of the blood.

SCIENCE IN THE SCHOOLS

One of the important problems to-day is how far science taught in schools can replace that taught in the first year of the medical curriculum. A great complaint regarding the teaching of the sciences in schools is that the teachers have to cater for a number of men whose intended occupations are very diverse, and it cannot be expected that the science taught can have any particular bias. It should, however, become generally known that, quite apart from bias, it is most unwise for medical students to take their chemistry and physics at school, especially if they do no biology at the same time, since they find themselves for a year with biology on their hands. The universities have been placed in the unfortunate position of receiving students some of whom have studied chemistry and physics at school and some who have not. It becomes necessary to provide for both, and much additional teaching is required. This reacts on the staff, since excessive teaching reduces time for research and makes the ablest men avoid such posts. It would probably be best if Medicine took a firm stand and established a subject of medical chemistry which included not only organic but also physical chemistry, a subject which is becoming increasingly important in the study of physiological processes. Further, intermediate chemistry for a science degree as it at present exists should not be allowed to exempt from medical chemistry, which would then be much more adapted and useful for medical needs. Let it be said at once that this medical chemistry would not in any way be easier than intermediate science chemistry, rather the reverse. Then might follow medical physics and medical biology, which would be a much more useful introduction to medicine than diluted science courses. The revised curriculum of the Conjoint Board is a definite step in the right direction, but it would have been better still if it had not allowed details—even details of medical interest—to obscure the great biological principles which are so important in real education.

RECENT MEDICAL ADVANCES

The great advances in medicine in the last fifty years have shown an interesting grouping. First came the study of pathology, which from investigations post mortem gradually established certain principles by which primary disease in one organ may affect another, and by which it was shown that certain symptoms probably depended on certain pathological lesions. In these days we are inclined to forget the pathologists of fifty to a hundred years ago who, with the aid of often very indifferent microscopes, laboriously searched the organs of the body for evidence of disease, the cause of which was unknown. Often their researches were unrewarded, but with each new advance we are beginning to realize what valuable work they did. But the great work of the pathologists was overshadowed in the later part of the last century by the bacteriologists, who followed in the footsteps of Lister and Pasteur. The bacteriologists demonstrated the bacterial origin of many diseases and treatment on anti-bacterial lines.

In the post-war era the advances have been due to physiology and biochemistry, and the discovery that a large amount of disease can be elucidated by the investigation of normal function. Unfortunately, as a physiologist, I cannot claim that all these advances have been made directly by professional physiologists. The discovery of the successful treatment of diabetes, pernicious anaemia, and rickets was not made by physiologists, but they depended entirely on methods of investigation which had been elaborated in the physiological and biochemical laboratory. It is almost impossible for any new investigation into the causation of any disease to proceed without frequent resort to recent physiological and biochemical literature, and, as we have indicated, the day is dawning when a systematic study of symptomatology with a basis on these subjects will take its place as an indispensable preliminary to the study of medicine and surgery.

THE SCIENCES BENEFIT STILL FROM MEDICINE

It has been said that the art of medicine is national, but that the science of medicine is international, because it stands on the firmer basis of the preliminary sciences, which have certain conventional fixed points. Nothing is more interesting or surprising than to learn how very differently the practitioners of different countries treat many complaints. We no longer look upon the preliminary sciences as being preliminary except in time; they are really auxiliary. We need chemists, physicists, and biologists interested in the problems of physiology and pathology just as we need experienced anatomists, physiologists, biochemists, and pathologists investigating the problems of medicine and surgery. Nor will the sciences suffer thereby; physiology and biochemistry have still much to learn from medicine and surgery. Our knowledge, for example, of carbohydrate metabolism owes much to the study of diabetes; our knowledge of the ductless glands and of the nervous system owes an enormous amount to clinical observation, and the astuteness of the clinician will always be a potent factor in physiological advance. In turn physiology and biochemistry enrich the subject of chemistry and even physics. The oxidation of fats in the body gave chemists a new conception of oxidation processes, while the principle of the string galvanometer, invented by a physiologist, is now extensively used in physics.

It is becoming increasingly common for medical students to supplement their training by taking a science degree in physiology, usually immediately after anatomy and physiology. A physiologist may be accused of emphasizing his own subject, and to a parent the extra year may appear an extravagance. A glance at the subsequent records of students who have taken this additional course shows most clearly how they stand out beyond their fellows, while it is interesting that many of the great leaders of medical science have been among them. Judging by results, then, it can be stated that the extra year is a good investment. The staffs of our universities are recruited largely from such men, and it is they who, by their knowing a little more of the sciences than their colleagues, may be expected to make use of them in the interest of medicine.

THE DUTY OF THE ADMINISTRATOR

Medical education has been slowly evolved, and those who guide it have a great responsibility. It is they who have to say, not that this or that piece of knowledge is valuable, but whether in a given time it is profitable to learn this piece or that; whether, for example, it is more profitable to learn the structure of a plant root, however interesting, or to require a higher standard of knowledge

regarding growth and repair, or to learn why a cardiac patient is breathless

Too often the faculties concerned simply allocate times to definite subjects, and leave the syllabus to the teachers concerned The variety of teaching evident from the syllabuses of various schools indicates the chaos which exists In medicine we know well that when there is a variety of treatments for the same complaint there is something very unsatisfactory about each treatment The difficulty, of course, is that those concerned with final year subjects are a little diffident in advising on subjects about which they admittedly know practically nothing, but many first year teachers would welcome some better attempt to advise them more definitely than is done by the General Medical Council, which is also too remote to give adequate advice In ignoring the syllabus a duty to the medical student is shirked The medical student is the future custodian of our profession and he must not be allowed to muddle through, guided more by the vested interests of the departments concerned than by the real need of his profession He must be encouraged to develop his sense of values and to weigh evidence, in the hope that he will one day add his quota to the sum of human knowledge, and be all the more capable of preventing and alleviating human suffering

Medicine must put its house in order, but those who are most immediately and personally interested in the advance of medical science are seldom the administrators Each administrator might well ask himself, Could I improve the early training of the medical student to equip him better for my own particular specialty? This question he could invariably answer in the affirmative and if he tries to imagine the other specialties he can easily realize that vast changes in the curriculum are really needed Probably the best preliminary science course could be secured if a specialist in each branch of medicine, of surgery, and of public health, well versed in research in his subject as well as in the applied side, was asked what he needed to be taught in the best interest of his specialty, and if these were subsequently welded together then could be added the subjects of cultural value at suitable periods

It has often been suggested that the student would appreciate the science more if he did some clinical work in his early years, but this is probably not so Some schools allow, or used to allow, the men to attend surgical out patients before they had completed anatomy and physiology, but there can be no doubt that the clinical work proved too strong a distraction to men who were visiting for the first time the pleasure of doing something useful, and was definitely detrimental to their more academic studies Experience however shows that the junior student, like the general practitioner, is appreciative, as shown by attendance at voluntary classes, of properly chosen instruction in the preliminary sciences

CULTURE IN MEDICINE

One word about culture in medicine Doctors have often been rather sensitive about being called the worst educated profession, although with the increasing number of men whose education is chiefly scientific the accusation loses much force The term "education" is surrounded by certain conventional ideas born of the school room and in the average university it is bolstered up by vested interests To consider an Arts professor who knows nothing of the natural sciences, or of the functions of his own body, or very little of human nature and quality better educated than a doctor is simply convention and nonsense, for if the limitations of time have made it necessary that the doctor is weak in his classics or history, or his literature, he has gained a vast and varied knowledge of nature which would be of inestimable value to his Arts colleague Probably the best purely cultural subject for the medical student is the history of medicine, by which he is brought to learn to be grateful for his heritage to learn of the years and years of patient endeavour which have led to the discovery of facts which he now considers commonplace, and to realize that he, too may make a modest contribution, whatever his sphere It is a most remarkable fact that medicine is one of the few professions which does not make an elementary study of its history obligatory on those who intend to adopt it, to maintain its traditions, and to reap its rewards

ECONOMICS IN MEDICINE

The preliminary sciences of medicine have to face another problem, which is one of economics There is a Scottish saying that 'the man who pays the piper calls the tune Medicine is entitled to call the tune, and history shows full well that it is generous to the sciences which serve it so well The present strong position of the medical sciences with their associated laboratories is due largely to medicine Medicine realizes full well that the independent anatomist, embryologist, histologist, physiologist biochemist, and pharmacologist justify their existence because of their researches, *provided* they do not forget altogether that they owe much of their welfare to the medical student

This problem is not confined to the medical sciences, but concerns also the older sciences of chemistry and physics, which have also tended to forget the hand that feeds The scientific industries found that the universities were not sufficiently elastic in their outlook, and largely ignored their needs, with the result that they themselves have established laboratories, often better equipped and with staffs better paid than in the universities and so these laboratories have become a strong counter attraction to university life Even the great pharmaceutical chemists have done likewise, to the detriment of the pharmacological laboratories in our universities To think of what many of our scientific departments might have become had they been more willing to assist industry makes us weep for the land of the might have been It is not too late There is no reason why the worker in applied science should not work side by side with the worker in pure science, indeed, both would gain considerably Were the universities really willing as a whole, industry could be made to realize that it is much more economical to endow workers and laboratories in the universities than to establish its own laboratories, in which the workers are more isolated and have not the advantage of discussion of their problems with the diversity of persons to be found in a university

The co operation between science and industry in the universities is much better seen in some other countries than in our own, and of recent years workers in industrial laboratories have made important contributions to pure science We shall see in the near future the foundation of schools of industrial science which will compete with universities for students, if the universities do not recognize this danger

COMPETITION BETWEEN DEPARTMENTS

Unfortunately, for similar reasons there is arising a competition among departments of medicine I refer particularly to the establishment of medical and surgical departments with extensive laboratories which correspond to the laboratories of industry In these departments is duplicated a large amount of apparatus in part time use in physiological and biochemical departments and indeed I know of some medical departments infinitely better equipped in physiological apparatus than the physiological laboratory in the same school But what is still more serious,

the senior departments, by offering greater emoluments, are having first option on the few men willing to take up academic life. In a medical department they may do exactly the same research work as in a physiological department, but they are better paid in the former. Biochemistry, which might be so much more valuable, has undoubtedly suffered particularly from the anxiety of non-medical biochemists to demonstrate their independence of medicine, forgetful of the fact that *every department of science, unless endowed, lives upon an applied science, through which it serves the community*. Biochemistry, it is true, has applications other than medical, but these are insufficient to induce students to study this new science in numbers large enough to maintain it. The result of this attitude of the biochemist is to discourage the foundation of chairs of biochemistry. The hospitals appoint their own biochemists to supply their needs, and academic biochemical departments are scarcely cognizant of the problems which present themselves in the wards. How much better it would have been for biochemistry and for its students if these hospital biochemists had been on the staff of departments of biochemistry. Now biochemistry has to content itself by attempting the impossible—to take over certain chemical parts of physiology. It is beginning to consider that digestion and metabolism, and even more, are its own particular preserve, and appears to imagine that these processes can be studied with little reference to the body as a whole or without any knowledge of the nervous system which controls them.

An unduly independent attitude of the preclinical sciences must lead to their own impairment, for they cannot escape from the ordinary economic laws. The lack of sympathy between purely scientific and medical departments is, however, not only of growing economic importance, but creates a vicious circle which tends to increase lack of sympathy, and the student is very adversely affected. At present the organic chemist teaches certain methods for certain tests and estimations; these are re-taught in another way by the biochemist, and again in still another way by the hospital biochemist. The medical student naturally considers that the methods which have the nearest relation to practical affairs are best, and does not have his opinion of his earlier teachers enhanced. This opinion he will never lose.

It would be well if the words of the late A. D. Waller were better known. They were spoken of physiology, but are applicable to all the medical sciences.

"Physiology must be studied for its own sake, but the physiologist whose immediate motive is *the want to know* may not deny his debt of service to the community of which he forms a part and whose services he enjoys, and the channel through which he can repay some part of that debt lies first of all in the service he may be able to render to the practice of medicine, to the knowledge and power of the physician whose immediate motive is the *want to help*."

THE PROFESSION OF MEDICINE

INTRODUCTORY

In accordance with long-standing custom we publish now, some weeks before the opening of the winter session at the medical schools, a special Educational Number. The form and contents of this annual issue have been modified from time to time, but its purpose remains unchanged, and the seasoned medical reader must expect to find here a great many familiar facts and phrases. The first object of the Educational Number is to give prospective students and their parents full information about the steps that must be taken in order to become a registered medical practitioner. The second object is to assist those wishing to know what a medical career has to offer, and others who, having already decided to study medicine, are uncertain about the line of work for which they are best suited. Our purpose is to supply information rather than to offer advice; but, as in past years, this introductory article gives an opportunity of reviewing some aspects and tendencies of medical study and practice, and of directing attention to a few points which might not occur to anyone without some experience of the medical life.

Intending students will find in the pages that follow an account of the course of training required of them, the places where it can be obtained, and the universities and other licensing bodies which test the knowledge gained and confer degrees or diplomas entitling successful candidates to become legally qualified medical practitioners. Sections are included also on post-graduate medical study, on the higher qualifications, both general and special, and on the many and varied spheres of work open to registered medical men and women at home and abroad. The details given are founded on official information, and arranged along the customary lines.

It may be well to repeat here, what has often been said before, that the aim of a medical education is to impart not only the essentials of medicine, but also the right principles and methods of adding to knowledge after qualification. Such teaching, to be effective, presupposes a good general education. Next in importance is a good scientific education—a thorough grounding in the basic principles of science. Upon these the student of ordinary intelligence and industry can build up an adequate technical equipment for the practice of his profession. An unfortunate tendency in studying the preliminary subjects is to acquire a mere "cram" knowledge, quickly forgotten after the particular examination is passed. These sciences interlock with each other and with the later subjects, and, properly approached, they give a drilling in exact methods and vigorous reasoning which will bear immediate fruit in the clinical part of the curriculum. Chemistry, physics, and elementary biology prepare the way for anatomy and physiology, and so for medicine and surgery and obstetrics. The curriculum is not perfect. It is always undergoing revision, to keep pace with new knowledge and improvements in practice. But all authorities are agreed that the preliminary and intermediate sciences form the only appropriate introduction to the study of clinical medicine, and attempts are made from time to time to bring the teaching of these subjects into closer relation with the life-work of the practitioner.

PORTALS OF THE PROFESSION

The obvious goal of every student is the entry of his name in the *Medical Register*, which is the official statutory list of qualified medical practitioners kept by the General Medical Council. There are many ways in which admission can be obtained to the *Register*. No fewer than twenty-seven bodies—eighteen universities and nine corporations—either separately or jointly issue registrable qualifications; and the number of teaching institutions is even larger. Nevertheless, although in this country we have no single State examination in medicine—no "conportal system"—the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same for all students. As, however, the individual teach-

ing and examining bodies have different standards and requirements, the choice should be made early, so that a definite plan may be followed.

The decision to study for a university degree in medicine should, if possible, be made by the time a boy or girl is 15. A matriculation examination or its equivalent should be attempted without delay, and the parent should ensure that the special requirements of the medical faculty of the selected university are fulfilled. As soon as this examination is disposed of work should be begun at school in the subjects of the First M.B. Few house-masters at public schools seem to be adequately informed about medical requirements under the revised curriculum, and it is doubtful if all schools are fully competent to meet the varying requirements of different authorities. Parents should therefore make inquiries on their own account in order that valuable time may not be wasted during the last year or two at school. This applies to all prospective medical students, but with special force to those seeking degrees at Oxford or Cambridge.

The conditions with which those who wish to enter the profession must comply are regulated by the General Medical Council, which is a statutory body set up under the Medical Acts; a summary of its functions and requirements is given at page 419. Many changes have lately been made in the medical and pre-medical curriculum, and this section, as well as the article on Professional Study and Examination, should be studied with care. It is the business of the General Medical Council, so far as possible, to see that a suitable kind of training and the requisite degree of knowledge are secured to the student, and it is the business of the medical schools and examining bodies to give the training and test the knowledge in accordance with the requirements of that Council. Every student, after passing examinations in the subjects of general education and in the preliminary sciences of chemistry and physics, must take a course of training at a recognized medical school, covering a period of at least five years, but usually extended to six years or more.

Examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. The requirements of these licensing bodies are summarized elsewhere under separate headings. One of the functions of the General Medical Council, besides that of keeping the *Medical Register* and maintaining discipline within the profession, is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses at approved institutions. Successful candidates eventually receive either degrees, in the case of a university, or diplomas or licences, in the case of a corporation; these qualifications entitle them to claim insertion of their names in the *Medical Register*. Every student, as soon as he obtains his qualification to practise, should at once register; otherwise he cannot hold a public medical appointment, or sign any certificate required from a legally qualified practitioner (such as a death certificate), or recover professional fees in a court of law.

Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied during the present century, and so many practitioners are now graduates in medicine that a student at the threshold of his career will do well to consider the advantages of possessing a degree, though it may be desirable to take also a diploma or licence. The medical degrees (M.B., M.D., etc.) granted by the universities in Great Britain and Ireland are mentioned among the particulars about each university printed in later sections.

COST OF MEDICAL EDUCATION

To those who have already decided to send their sons into the medical profession, no less than to those who are weighing the matter, a few words on the cost of medical education may prove helpful. For the ordinary student this resolves itself into the cost of the training at medical school and hospital, and the cost of living during the five or six years of the curriculum. The expenses under these two main headings vary considerably. Besides differences in the charges made for instruction, there are differences in examination fees, as well as in the fees for certificates of qualification, and those who seek the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again, not all students have the knack of imparting what they know to an examiner, and every setback due to failure in the examination room or to illness means added expenses. School and examination fees, together with the cost of board, lodging, clothes, and recreation, form the largest items of expenditure, and to these must be added the money spent on books, microscope, instruments, and so forth.
